TOC 2

With any interactive computer language, the user interacts with the system through an "executive", which interprets and executes typed-in commands. In most implementations of Lisp, the executive is a simple "read-eval-print" loop, which repeatedly reads a Lisp expression, evaluates it, and prints out the value of the expression. Interlisp has an executive which allows a much greater range of inputs, other than just regular Interlisp expressions.

In particular, the Interlisp executive implements a facility known as the "programmer's assistant" (or "p.a."). The central idea of the programmer's assistant is that the user is addressing an active intermediary, namely his assistant. Normally, the assistant is invisible to the user, and simply carries out the user's requests. However, the assistant remembers what the user has done, so the user can give commands to repeat a particular operation or sequence of operations, with possible modifications, or to undo the effect of specified operations. Like DWIM, the programmer's assistant embodies an approach to system design whose ultimate goal is to construct an environment that "cooperates" with the user in the development of his programs, and frees him to concentrate more fully on the conceptual difficulties and creative aspects of the problem at hand.

The programmer's assistant facility features the use of memory structures called "history lists." A history list is a list of the information associated with each of the individual "events" that have occurred in the system, where each event corresponds to one user input. Associated with each event on the history list is the input and its value, plus other optional information such as side-effects, formatting information, etc.

The following dialogue, taken from an actual session at the terminal, contains illustrative examples and gives the flavor of the programmer's assistant facility in Interlisp. The number before each prompt is the "event number" (see page 13.31).

12←(SETQ FOO 5) 5 13←(SETQ FOO 10) (FOO reset) 10

The p.a. notices that the user has reset the value of FOO and informs the user.

14←UNDO

SETQ undone.

15←FOO<sup>cr</sup>

5

This is the first example of direct communication with the p.a. The user has said to UNDO the previous input to the executive.

25←SET(LST1 (A B C))

(A B C)

26←(SETQ LST2 '(D E F))

(D E F)

27←(FOR X IN LST1 DO (REMPROP X 'MYPROP]

NIL

The user asked to remove the property MYPROP from the atoms A, B, and C. Now lets assume that is not what he wanted to do, but rather use the elements of LST2.

#### 28←UNDO FOR

FOR undone.

First he undoes the REMPROP, by undoing the iterative statement. Notice the UNDO accepted an "argument," although in this case UNDO by itself would be sufficient.

#### 29←USE LST2 FOR LST1 IN 27

NIL

The user just instructed to go back to event number 27 and substitute LST2 for LST1 and then reexecute the expression. The user could have also specified -2 instead of 27 to specify a relative address.

47←(PUTHASH 'FOO (MKSTRING 'FOO) MYHASHARRAY) "FOO"

If MKSTRING was a computationally expensive function (which it is not), then the user might be cacheing its value for later use.

48←USE FIE FUM FOE FOR FOO IN MKSTRING

"FIE"

"FUM"

"FOE"

The user now decides he would like to redo the PUTHASH several times with different values. He specifies the event by "IN MKSTRING" rather than PUTHASH.

49←?? USE

48. USE FIE FUM FOE FOR FOO IN MKSTRING ←(PUTHASH (QUOTE FIE) (MKSTRING (QUOTE FIE)) MYHASHARRAY)

```
"FIE"
←(PUTHASH (QUOTE FUM) (MKSTRING (QUOTE FUM))
MYHASHARRAY)
"FUM"
←(PUTHASH (QUOTE FOE) (MKSTRING (QUOTE FOE))
MYHASHARRAY)
"FOE"
```

Here we see the user ask the p.a. (using the ?? command) what it has on its history list for the last input to the executive. Since the event corresponds to a programmer's assistant command that evaluates several forms, these forms are saved as the input, although the user's actual input, the p.a. command, is also saved in order to clarify the printout of that event.

As stated earlier, the most common interaction with the programmer's assistant occurs at the top level read-eval-print loop, or in a break, where the user types in expressions for evaluation, and sees the values printed out. In this mode, the assistant acts much like a standard Lisp executive, except that before attempting to evaluate an input, the assistant first stores it in a new entry on the history list. Thus if the operation is aborted or causes an error, the input is still saved and available for modification and/or reexecution. The assistant also notes new functions and variables to be added to its spelling lists to enable future corrections. Then the assistant executes the computation (i.e., evaluates the form or applies the function to its arguments), saves the value in the entry on the history list corresponding to the input, and prints the result, followed by a prompt character to indicate it is again ready for input.

If the input typed by the user is recognized as a p.a. command, the assistant takes special action. Commands such as UNDO and ?? are immediately performed. Commands that involved reexecution of previous inputs, such as REDO and USE, are achieved by computing the corresponding input expression(s) and then unreading them. The effect of this unreading operation is to cause the assistant's input routine, LISPXREAD, to act exactly as though these expressions were typed in by the user. These expressions are processed exactly as though they had been typed, except that they are not saved on new and separate entries on the history list, but associated with the history command that generated them.

# 13.1 Input Formats

The Interlisp-D executive accepts inputs in the following formats:

INTERLISP EXECUTIVE 13.3

**EVALV-format input** 

If the user types a single litatom, followed by a carriage-return, the value of the litatom is returned. For example, if the value of the variable FOO is the list (A B C):

←FOO<sup>cr</sup> (A B C)

**EVAL-format input** 

If the user types a regular Interlisp expression, beginning with a left parenthesis or square bracket and terminated by a matching right parenthesis or square bracket, the form is simply passed to EVAL for evaluation. A right bracket matches any number of left parentheses, back to the last left bracket or the entire expression. Notice that it is not necessary to type a carriage return at the end of such a form; Interlisp will supply one automatically. If a carriage-return is typed before the final matching right parenthesis or bracket, it is treated as a space, and input continues. The following examples are all interpreted the same:

←(PLUS 1 (TIMES 2 3))
7
←(PLUS 1 (TIMES 2 3]
7
←(PLUS 1 (TIMES<sup>Cr</sup>
2 3]

APPLY-format input

Often, the user, typing at the keyboard, calls functions with constant argument values, which would have to be quoted if the user typed it in "EVAL-format." For convience, if the user types a litatom immediately followed by a list form, the litatom is APPLYed to the elements within the list, unevaluated. The input is terminated by the matching right parenthesis or bracket. For example, typing LOAD(FOO) is equivalent to typing (LOAD 'FOO), and GETPROP(X COLOR) is equivalent to (GETPROP 'X 'COLOR).

APPLY-format input is useful in some situations, but note that it may produce unexpected results when an *nlambda* function is called that explicitly evaluates its arguments (see page 10.2). For example, typing SETQ(FOO BAR) will set FOO to the *value* of BAR, not to the litatom BAR itself.

Other input

Sometimes, a user does not want to terminate the input when a closing parenthesis is typed. For example, some programmer's assistant commands take several arguments, some of which can be lists. If the GET types a sequence of litatoms and lists beginning with a litatom and a space (to distinguish it from APPLY-format), terminated by a carriage return or an extra right parenthesis or bracket, the Interlisp-D executive interprets it differently depending on the number of expressions typed.

If only one expression is typed (a litatom), it is interpreted as an EVALV-format input, and the value of the litatom is returned:

# ←FOO<space><sup>cr</sup> (A B C)

If exactly two expressions are typed, it is interpreted as APPLY-format input:

```
←LIST (A B)<sup>C</sup>
(A B)
```

If three or more expressions are typed, it is interpreted as EVAL-format input. To warn the user, the full expression is printed out before it is executed. For example:

```
←PLUS (TIMES 2 3) 1 cr
= (PLUS (TIMES 2 3) 1)
7
```

Note: If LISPXREADFN (page 13.36) is set to READ (rather than the default, TTYINREAD), then whenever one of the elements typed is a list and the list is terminated by a right parenthesis or bracket, Interlisp will type a carriage-return and "..." to indicate that further input will be accepted. The user can type further expressions or terminate the whole expression by a carriage-return.

# 13.2 Programmer's Assistant Commands

The programmer's assistant recognizes a number of commands, which usually refer to past events on the history list. These commands are treated specially; for example, they may not be put on the history list.

Note: If the user defines a function by the same name as a p.a. command, a warning message is printed to remind him that the p.a. command interpretation will take precedence for type-in.

All programmer's assistant commands use the same conventions and syntax for indicating which event or events on the history list the command refers to, even though different commands may be concerned with different aspects of the corresponding event(s), e.g., side-effects, value, input, etc. Therefore, before discussing the various p.a. commands, the following section describes the types of event specifications currently implemented.

INTERLISP EXECUTIVE

## 13.2.1 Event Specification

An event address identifies one event on the history list. It consists of a sequence of "commands" for moving an imaginary cursor up or down the history list, much in the manner of the arguments to the @ break command (see page 14.6). The event identified is the one "under" the imaginary cursor when there are no more commands. (If any command fails, an error is generated and the history command is aborted.) For example, the event address 42 refers to the event with event number 42, 42 FOO refers to the first event (searching back from event 42) whose input contains the word FOO, and 42 FOO -1 refers to the event preceeding that event. Usually, an event address will contain only one or two commands.

Most of the event address commands perform searches for events which satisfy some condition. Unless the ← command is given (see below), this search always goes backwards through the history list, from the most recent event specified to the oldest. Note that each search skips the current event. For example, if FOO refers to event N, FOO FIE will refer to some event before event N, even if there is a FIE in event N.

The event address commands are interpreted as follows:

## N (an integer)

If N is the first command in an event address, refers to the event with event number N. Otherwise, refers to the event N events forward (in direction of increasing event number). If N is negative, it always refers to the event N events backwards.

For example, -1 refers to the previous event, 42 refers to event number 42 (if the first command in an event address), and 42 3 refers to the event with event number 45.

#### **←LITATOM**

Specifies the last event with an APPLY-format input whose function matches LITATOM.

Note: There must not be a space between  $\leftarrow$  and LITATOM.

- ← Specifies that the next search is to go forward instead of backward. If given as the first event address command, the next search begins with last (oldest) event on the history list.
- F Specifies that the next object in the event address is to be searched for, regardless of what it is. For example, F-2 looks for an event containing -2.
- Specifies that the next object (presumably a pattern) is to be matched against the values of events, instead of the inputs.
- \ Specifies the event last located.

#### **SUCHTHAT PRED**

Specifies an event for which the function *PRED* returns true. *PRED* should be a function of two arguments, the input portion of the event, and the event itself. See page 13.31 for a discussion of the format of events on the history list.

PAT Any other event address command specifies an event whose input contains an expression that matches PAT as described in page 16.18.

The matching is performed by the function HISTORYMATCH (page 13.40), which is initially defined to call **EDITFINDP** but can be advised or redefined for specialized applications.

Note: Symbols used below of the form *EventAddress*; refer to event addresses, described above. Since an event address may contain multiple words, the event address is parsed by searching for the words which delimit it. For example, in FROM *EventAddress*; THRU *EventAddress*; the symbol *EventAddress*; corresponds to all words between FROM and THRU in the event specification, and *EventAddress*; to all words from THRU to the end of the event specification.

## FROM EventAddress<sub>1</sub> THRU EventAddress<sub>2</sub>

EventAddress<sub>1</sub> THRU EventAddress<sub>2</sub>

Specifies the sequence of events from the event with address *EventAddress*<sub>1</sub> through the event with address *EventAddress*<sub>2</sub>. For example, FROM 47 THRU 49 specifies events 47, 48, and 49. *EventAddress*<sub>1</sub> can be more recent than *EventAddress*<sub>2</sub>. For example, FROM 49 THRU 47 specifies events 49, 48, and 47 (note reversal of order).

## FROM EventAddress 1 TO EventAddress 2

EventAddress<sub>1</sub> TO EventAddress<sub>2</sub>

Same as THRU but does not include event EventAddress 2.

FROM EventAddress 1

Same as FROM EventAddress<sub>1</sub> THRU -1. For example, if the current event is number 53, then FROM 49 specifies events 49, 50, 51, and 52.

THRU EventAddress >

Same as FROM -1 THRU EventAddress<sub>2</sub>. For example, if the current event is number 53, then THRU 49 specifies events 52, 51, 50, and 49 (note reversal of order).

TO EventAddress<sub>2</sub>

Same as FROM -1 TO EventAddress 2.

ALL EventAddress 1

Specifies all events satisfying *EventAddress*<sub>1</sub>. For example, ALL **LOAD**, ALL SUCHTHAT FOO.

empty

If nothing is specified, it is the same as specifying -1.

Note: In the special case that the last event was an UNDO, it is the same as specifying -2. For example, if the user types (NCONC FOO FIE), he can then type UNDO, followed by USE NCONC1.

#### EventSpec<sub>1</sub> AND EventSpec<sub>2</sub> AND ... AND EventSpec<sub>N</sub>

Each of the *EventSpec*; is an event specification. The lists of events are concatenated. For example, FROM 30 THRU 32 AND 35 THRU 37 is the same as 30 AND 31 AND 32 AND 35 AND 36 AND 37.

@ LITATOM

If *LITATOM* is the name of a command defined via the **NAME** command (page 13.14), specifies the event(s) defining *LITATOM*.

### @@ EventSpec

EventSpec is an event specification interpreted as above, but with respect to the archived history list (see the ARCHIVE command, page 13.16).

If no events can be found that satisfy the event specification, spelling correction on each word in the event specification is performed using LISPXFINDSPLST as the spelling list. For example, REDO 3 THRUU 6 will work correctly. If the event specification still fails to specify any events after spelling correction, an error is generated.

## 13.2.2 Commands

All programmer's assistant commands can be input as list forms, or as lines (see page 13.36). For example, typing REDO 5<sup>cr</sup> and (REDO 5) are equivalent.

EventSpec is used to denote an event specification. Unless specified otherwise, omitting EventSpec is the same as specifying EventSpec = -1. For example, REDO and REDO -1 are the same.

#### **REDO** EventSpec

[Prog. Asst. Command]

Redoes the event or events specified by *EventSpec*. For example, REDO FROM -3 redoes the last three events.

#### REDO EventSpec N TIMES

[Prog. Asst. Command]

Redoes the event or events specified by *EventSpec N* times. For example, REDO 10 TIMES redoes the last event ten times.

#### **REDO** EventSpec WHILE FORM

[Prog. Asst. Command]

Redoes the specified events as long as the value of *FORM* is true. *FORM* is evaluated before each iteration so if its initial value is **NIL**, nothing will happen.

## REDO EventSpec UNTIL FORM

[Prog. Asst. Command]

Same as REDO EventSpec WHILE (NOT FORM).

#### REPEAT EventSpec

[Prog. Asst. Command]

Same as REDO EventSpec WHILE T. The event(s) are repeated until an error occurs, or the user types control-E or control-D.

## REPEAT EventSpec WHILE FORM

[Prog. Asst. Command]

## REPEAT EventSpec UNTIL FORM

[Prog. Asst. Command]

Same as REDO.

For all history commands that perform multiple repetitions, the variable **REDOCNT** is initialized to 0 and incremented each iteration. If the event terminates gracefully, i.e., is not aborted by an error or control-D, the number of iterations is printed.

#### RETRY EventSpec

[Prog. Asst. Command]

Similar to **REDO** except sets **HELPCLOCK** (page 14.14) so that any errors that occur while executing *EventSpec* will cause breaks.

#### **USE EXPRS FOR ARGS IN EventSpec**

[Prog. Asst. Command]

Substitutes EXPRS for ARGS in EventSpec, and redoes the result. Substitution is done by ESUBST (page 16.73), and is carried out as described below. EXPRS and ARGS can include non-atomic members.

For example, USE LOG (MINUS X) FOR ANTILOG X IN -2 AND -1 will substitute LOG for every occurrence of ANTILOG in the previous two events, and substitute (MINUS X) for every occurrence of X, and reexecute them. Note that these substitutions do not change the information saved about these events on the history list.

Any expression to be substituted can be preceded by a !, meaning that the expression is to be substituted as a segment, e.g., LIST(A B C) followed by USE! (X Y Z) FOR B will produce LIST(A X Y Z C), and USE! NIL FOR B will produce LIST(A C).

If IN EventSpec is omitted, the first member of ARGS is used for EventSpec. For example, USE PUTD FOR @UTD is equivalent to USE PUTD FOR @UTD IN F @UTD. The F is inserted to handle correctly the case where the first member of ARGS could be interpreted as an event address command.

## **USE EXPRS IN EventSpec**

[Prog. Asst. Command]

If ARGS are omitted, and the event referred to was itself a USE command, the arguments and expression substituted into are the same as for the indicated USE command. In effect, this USE command is thus a continuation of the previous USE command. For example, following USE X FOR Y IN 50, typing USE Z IN -1 is equivalent to USE Z FOR Y IN 50.

If ARGS are omitted and the event referred to was not a USE command, substitution is for the "operator" in that command. For example ARGLIST(FF) followed by USE CALLS IN -1 is equivalent to USE CALLS FOR ARGLIST IN -1.

If IN EventSpec is omitted, it is the same as specifying IN -1.

## USE EXPRS 1 FOR ARGS 1 AND ... AND EXPRS N FOR ARGS N IN EventSpec

[Prog. Asst.

#### Command]

More general form of USE command. See description of the substitution algorithm below.

Note: The USE command is parsed by a small finite state parser to distinguish the expressions and arguments. For example, USE FOR FOR AND AND FOR FOR will be parsed correctly.

Every USE command involves three pieces of information: the expressions to be substituted, the arguments to be substituted for, and an event specification, which defines the input expression in which the substitution takes place. If the USE command has the same number of expressions as arguments, the substitution procedure is straightforward. For example, USE X Y FOR U V means substitute X for U and Y for V, and is equivalent to USE X FOR U AND Y FOR V. However, the USE command also permits distributive substitutions, for substituting several expressions for the same argument. For example, USE A B C FOR X means first substitute A for X then substitute B for X (in a new copy of the expression), then substitute C for X. The effect is the same as three separate USE commands. Similarly, USE A B C FOR D AND X Y Z FOR W is equivalent to USE A FOR D AND X FOR W, followed by USE B FOR D AND Y FOR W, followed by USE C FOR D AND Z FOR W. USE A B C FOR D AND X FOR Y also corresponds to three substitions, the first with A for D and X for Y, the second with B for D, and X for Y, and the third with C for D, and again X for Y. However, USE A B C FOR D AND X Y FOR Z is ambiguous and will cause an error. Essentially, the USE command operates by proceeding from left to right handling each "AND" separately. Whenever the number of expressions exceeds the number of expressions available, multiple USE expressions are generated. Thus USE A B C D FOR E F means substitute A for E at the same time as substituting B for F, then in another copy of the indicated expression, substitute C for E and D for F. Note that this is also equivalent to USE A C FOR E AND B D FOR F.

Note: Parsing the USE command gets more complicated when one of the arguments and one of the expressions are the same, e.g., USE X Y FOR Y X, or USE X FOR Y AND Y FOR X. This situation is noticed when parsing the command, and handled correctly.

... VARS

[Prog. Asst. Command]

Similar to **USE** except substitutes for the (first) operand.

For example, EXPRP(FOO) followed by ... FIE FUM is equivalent to USE FIE FUM FOR FOO.

Note: In the following discussion, \$ is used to represent the character "escape," since this is how this character is echoed.

#### **\$** X FOR Y IN EventSpec

[Prog. Asst. Command]

\$ (escape) is a special form of the USE command for conveniently specifying *character* substitutions in litatoms or strings. In addition, it has a number of useful properties in connection with events that involve errors (see below).

Equivalent to **USE** \$X\$ **FOR** \$Y\$ **IN** *EventSpec*, which will do a character substitution of the characters in X for the characters in Y.

For example, if the user types MOVD(FOO FOOSAVE T), he can then type \$ FIE FOR FOO IN MOVD to perform MOVD(FIE FIESAVE T). Note that USE FIE FOR FOO would perform MOVD(FIE FOOSAVE T).

#### \$ Y X IN EventSpec

[Prog. Asst. Command]

#### **\$** YTO XIN EventSpec

[Prog. Asst. Command]

#### Y = XIN EventSpec

[Prog. Asst. Command]

#### \$ Y -> X IN EventSpec

[Prog. Asst. Command]

Abbreviated forms of the \$ (escape) command: the same as \$ X FOR Y IN EventSpec, which changes Ys to Xs.

\$ does event location the same as the USE command, i.e., if IN EventSpec is not specified, \$ searches for Y. However, unlike USE, \$ can only be used to specify one substitution at a time. After \$ finds the event, it looks to see if an error was involved in that event, and if the indicated character substitution can be performed in the object of the error message, called the offender. If so, \$ assumes the substitution refers to the offender, performs the indicated character substitution in the offender only, and then substitutes the result for the original offender throughout the event. For example, suppose the user types (PRETTYDEF FOOFNS 'FOO FOOOVARS) causing a U.B.A. FOOOVARS error message. The user can now type \$ OO O, which will change FOOOVARS to FOOVARS, but not change FOOFNS or FOO.

If an error did occur in the specified event, the user can also omit specifying the object of the substitution, Y, in which case the offender itself is used. Thus, the user could have corrected the above example by simply typing \$ FOOVARS. Since ESUBST is used for performing the substitution (see page 16.73), \$ can be used in X to refer to the characters in Y. For example, if the user

types LOAD(PRSTRUC PROP), causing the error FILE NOT FOUND PRSTRUC, he can request the file to be loaded from LISP's directory by simply typing \$ <LISP>\$. This is equivalent to performing (R PRSTRUC <LISP>\$) on the event, and therefore replaces PRSTRUC by <LISP>PRSTRUC.

Note that \$ never searches for an error. Thus, if the user types LOAD(PRSTRUC PROP) causing a FILE NOT FOUND error, types CLOSEALL(), and then types \$ <LISP>\$, LISPX will complain that there is no error in CLOSEALL(). In this case, the user would have to type \$ <LISP>\$ IN LOAD, or \$ PRS <LISP>PRS (which would cause a search for PRS).

Note also that \$ operates on *input*, not on programs. If the user types FOO(), and within the call to FOO gets a U.D.F. CONDD error, he *cannot* repair this by \$ COND. LISPX will type CONDD NOT FOUND IN FOO().

### FIX EventSpec

[Prog. Asst. Command]

Envokes the default program editor (Dedit or the teletype editor) on a copy of the input(s) for *EventSpec*. Whenever the user exits via **OK**, the result is unread and reexecuted exactly as with **REDO**.

**FIX** is provided for those cases when the modifications to the input(s) are not simple substitutions of the type that can be specified by **USE**. For example, if the default editor is the teletype editor, then:

←(DEFINEQ FOO (LAMBDA (X) (FIXSPELL SPELLINGS2 X 70] INCORRECT DEFINING FORM

FOO

←FIX

EDIT

\*P

(DEFINEQ FOO (LAMBDA & &))

\*(LI 2)

\*P

(DEFINEQ (FOO &))

\*OK

(FOO)

\_\_

The user can also specify the edit command(s) to LISPX, by typing - followed by the command(s) after the event specification, e.g., FIX - (LI 2). In this case, the editor will not type EDIT, or wait for an OK after executing the commands.

Note: FIX calls the editor on the "input sequence" of an event, adjusting the editor so it is initially editing the expression typed. However, the entire input sequence is being edited, so it is

possible to give editor commands that examine this structure further. For more information on the format of an event's input, see page 13.31.

#### ?? EventSpec

[Prog. Asst. Command]

Prints the specified events from the history list. If *EventSpec* is omitted, ?? prints the entire history list, beginning with most recent events. Otherwise ?? prints only those events specified in *EventSpec* (in the order specified). For example, ?? -1, ?? 10 THRU 15, etc.

For each event specified, ?? prints the event number, the prompt, the input line(s), and the value(s). If the event input was a p.a. command that "unread" some other input lines, the p.a. command is printed without a preceding prompt, to show that they are not stored as the input, and the input lines are printed with prompts.

Events are initially stored on the history list with their value field equal to the character "bell" (control-G). Thefore, if an operation fails to complete for any reason, e.g., causes an error, is aborted, etc., ?? will print a bell as its "value".

?? commands are not entered on the history list, and so do not affect relative event numbers. In other words, an event specification of -1 typed following a ?? command will refer to the event immediately preceding the ?? command.

?? is implemented via the function **PRINTHISTORY**, page 13.42, which can also be called directly by the user. Printing is performed via the function **SHOWPRIN2** (page 25.10), so that if the value of **SYSPRETTYFLG** = **T**, events will be prettyprinted.

#### UNDO EventSpec

[Prog. Asst. Command]

Undoes the side effects of the specified events. For each event undone, UNDO prints a message: RPLACA undone, REDO undone etc. If nothing is undone because nothing was saved, UNDO types nothing saved. If nothing was undone because the event(s) were already undone, UNDO types already undone.

If EventSpec is not given, UNDO searches back for the last event that contained side effects, was not undone, and itself was not an UNDO command. Note that the user can undo UNDO commands themselves by specifying the corresponding event address, e.g., UNDO -7 or UNDO UNDO.

In order to restore all pointers correctly, the user should **UNDO** events in the reverse order from which they were executed. For example, to undo all the side effects of the last five events, perform **UNDO THRU -5**, not **UNDO FROM -5**. Undoing out of order may have unforseen effects if the operations are

dependent. For example, if the user performed (NCONC1 FOO FIE), followed by (NCONC1 FOO FUM), and then undoes the (NCONC1 FOO FIE), he will also have undone the (NCONC1 FOO FUM). If he then undoes the (NCONC1 FOO FUM), he will cause the FIE to reappear, by virtue of restoring FOO to its state before the execution of (NCONC1 FOO FUM). For more details, see page 13.27.

## **UNDO** EventSpec: X<sub>1</sub> ... X<sub>N</sub>

[Prog. Asst. Command]

Each  $X_i$  is a pattern that is matched to a message printed by DWIM in the event(s) specified by *EventSpec*. The side effects of the corresponding DWIM corrections, and only those side effects, are undone.

For example, if DWIM printed the message PRINTT [IN FOO] -> PRINT, then UNDO: PRINTT or UNDO: PRINT would undo the correction.

Some portions of the messages printed by DWIM are strings, e.g., the message FOO UNSAVED is printed by printing FOO and then "UNSAVED". Therefore, if the user types UNDO: UNSAVED, the DWIM correction will not be found. He should instead type UNDO: FOO or UNDO: \$UNSAVED\$ (<esc>UNSAVED<esc>, see R command in editor, page 16.45).

#### NAME LITATOM EventSpec

[Prog. Asst. Command]

Saves the event(s) (including side effects) specified by *EventSpec* on the property list of *LITATOM* (under the property HISTORY). For example, NAME FOO 10 THRU 15. NAME commands are undoable.

Events saved on a litatom can be retrieved with the event specification @ LITATOM. For example, ?? @ FOO, REDO @ FOO, etc.

Commands defined by **NAME** can also be typed in directly as though they were built-in commands, e.g., **FOO**<sup>cr</sup> is equivalent to **REDO** @ **FOO**. However, if **FOO** is the name of a variable, it would be evaluated, i.e., **FOO**<sup>cr</sup> would return the value of **FOO**.

Commands defined by NAME can also be defined to take arguments:

NAME LITATOM (ARG<sub>1</sub> ... ARG<sub>N</sub>) : EventSpec

[Prog. Asst. Command]

NAME LITATOM ARG<sub>1</sub> ... ARG<sub>N</sub> : EventSpec

[Prog. Asst. Command]

The arguments  $ARG_i$  are interpreted the same as the arguments for a **USE** command. When *LITATOM* is invoked, the argument

values are substituted for  $ARG_1$  ...  $ARG_N$  using the same substitution algorithm as for USE.

**NAME FOO** EventSpec is equivalent to **NAME FOO**: EventSpec. In either case, if **FOO** is invoked with arguments, an error is generated.

For example, following the event (PUTD 'FOO (COPY (GETPROP 'FIE 'EXPR))), the user types NAME MOVE FOO FIE: PUTD. Then typing MOVE TEST1 TEST2 would cause (PUTD 'TEST1 (COPY (GETPROP 'TEST2 'EXPR))) to be executed, i.e., would be equivalent to typing USE TEST1 TEST2 FOR FOO FIE IN MOVE. Typing MOVE A B C D would cause two PUTD's to be executed. Note that !'s and \$'s can also be employed the same as with USE. For example, if following

- ←PREPINDEX(<MANUAL>14LISP.XGP)
- ←FIXFILE(<MANUAL>14LISP.XGPIDX)

the user performed NAME FOO \$14\$: -2 AND -1, then FOO \$15\$ would perform the indicated two operations with 14 replaced by 15.

#### RETRIEVE LITATOM

[Prog. Asst. Command]

Retrieves and reenters on the history list the events named by LITATOM. Causes an error if LITATOM was not named by a NAME command.

For example, if the user performs NAME FOO 10 THRU 15, and at some time later types RETRIEVE FOO, 6 new events will be recorded on the history list (whether or not the corresponding events have been forgotten yet). Note that RETRIEVE does not reexecute the events, it simply retrieves them. The user can then REDO, UNDO, FIX, etc. any or all of these events. Note that the user can combine the effects of a RETRIEVE and a subsequent history command in a single operation, e.g., REDO FOO is equivalent to RETRIEVE FOO, followed by an appropriate REDO. Actually, REDO FOO is better than RETRIEVE followed by REDO since in the latter case, the corresponding events would be entered on the history list twice, once for the RETRIEVE and once for the REDO. Note that UNDO FOO and ?? FOO are permitted.

#### **BEFORE LITATOM**

[Prog. Asst. Command]

Undoes the effects of the events named by LITATOM.

#### AFTER LITATOM

[Prog. Asst. Command]

Undoes a **BEFORE** LITATOM.

BEFORE and AFTER provide a convenient way of flipping back and forth between two states, namely the state before a specified event or events were executed, and that state after execution. For example, if the user has a complex data structure which he wants to be able to interrogate before and after certain modifications, he can execute the modifications, name the corresponding events with the NAME command, and then can turn these modifications off and on via BEFORE or AFTER commands. Both BEFORE and AFTER are no-ops if the LITATOM was already in the corresponding state; both generate errors if LITATOM was not named by a NAME command.

The alternative to **BEFORE** and **AFTER** for repeated switching back and forth involves typing **UNDO**, **UNDO** of the **UNDO**, **UNDO** of that etc. At each stage, the user would have to locate the correct event to undo, and furthermore would run the risk of that event being "forgotten" if he did not switch at least once per time-slice.

Note: Since UNDO, NAME, RETRIEVE, BEFORE, and AFTER are recorded as inputs they can be referenced by REDO, USE, etc. in the normal way. However, the user must again remember that the context in which the command is reexecuted is different than the original context. For example, if the user types NAME FOO DEFINEQ THRU COMPILE, then types ... FIE, the input that will be reread will be NAME FIE DEFINEQ THRU COMPILE as was intended, but both DEFINEQ and COMPILE, will refer to the most recent event containing those atoms, namely the event consisting of NAME FOO DEFINEQ THRU COMPILE.

## **ARCHIVE** EventSpec

[Prog. Asst. Command]

Records the events specified by *EventSpec* on a permanent "archived" history list, **ARCHIVELST** (page 13.31). This history list can be referenced by preceding a standard event specification with @@ (see page 13.8). For example, ?? @@ prints the archived history list, **REDO** @@ -1 will recover the corresponding event from the archived history list and redo it, etc.

The user can also provide for automatic archiving of selected events by appropriately defining ARCHIVEFN (page 13.23), or by putting the history list property \*ARCHIVE\*, with value T, on the event (page 13.33). Events that are referenced by history commands are automatically marked for archiving in this fashion.

#### FORGET EventSpec

[Prog. Asst. Command]

Permanently erases the record of the side effects for the events specified by *EventSpec*. If *EventSpec* is omitted, forgets side effects for entire history list.

FORGET is provided for users with space problems. For example, if the user has just performed SETs, RPLACAs, RPLACDs, PUTD, REMPROPs, etc. to release storage, the old pointers would not be garbage collected until the corresponding events age sufficiently to drop off the end of the history list and be forgotten. FORGET can be used to force immediate forgetting (of the side-effects only). FORGET is not undoable (obviously).

#### REMEMBER EventSpec

[Prog. Asst. Command]

Instructs the file package to "remember" the events specified by *EventSpec*. These events will be marked as changed objects of file package type **EXPRESSIONS**, which can be written out via the file package command **P**. For example, after the user types:

←MOVD?(DELFILE /DELFILE)

DELFILE

←REMEMBER -1

(MOVD? (QUOTE DELFILE) (QUOTE /DELFILE))

**←** 

If the user calls FILES?, MAKEFILES, or CLEANUP, the command (P (MOVD? (QUOTE DELFILE) (QUOTE /DELFILE))) will be constructed by the file package and added to the filecoms indicated by the user, unless the user has already explicitly added the corresponding expression to some P command himself.

Note that "remembering" an event like (PUTPROP 'FOO 'CLISPTYPE EXPRESSION) will not result in a (PROP CLISPTYPE FOO) command, because this will save the current (at the time of the MAKEFILE) value for the CLISPTYPE property, which may or may not be EXPRESSION. Thus, even if there is a PROP command which saves the CLISPTYPE property for FOO in some FILECOMS, remembering this event will still require a (P (PUTPROP 'FOO 'CLISPTYPE EXPRESSION)) command to appear.

#### PL LITATOM

[Prog. Asst. Command]

"Print Property List." Prints out the property list of *LITATOM* in a nice format, with **PRINTLEVEL** reset to (2.3). For example,

←PL +

CLISPTYPE: 12

**ACCESSFNS: (PLUS IPLUS FPLUS)** 

PL is implemented via the function PRINTPROPS.

#### **PB LITATOM**

[Prog. Asst. Command]

"Print Bindings." Prints the value of LITATOM with PRINTLEVEL reset to (2 . 3). If LITATOM is not bound, does not attempt spelling correction or generate an error. PB is implemented via the function PRINTBINDINGS.

**PB** is also a break command (page 14.8). As a break command, it ascends the stack and, for each frame in which *LITATOM* is bound, prints the frame name and value of *LITATOM*. If typed in to the programmer's assistant when not at the top level, e.g. in the editor, etc., **PB** will also ascend the stack as it does with a break. However, as a programmer's assistant command, it is primarily used to examine the top level value of a variable that may or may not be bound, or to examine a variable whose value is a large list.

#### ; FORM

## [Prog. Asst. Command]

Allows the user to type a line of text without having the programmer's assistant process it. Useful when linked to other users, or to annotate a dribble file (page 30.12).

#### SHH FORM

## [Prog. Asst. Command]

Allows the user to evaluate an expression without having the programmer's assistant process it or record it on a history list. Useful when one wants to bypass a programmer's assistant command or to keep the evaluation off the history list.

#### TYPE-AHEAD

## [Prog. Asst. Command]

A command that allows the user to type-ahead an indefinite number of inputs.

The assistant responds to TYPE-AHEAD with a prompt character of >. The user can now type in an indefinite number of lines of input, under ERRORSET protection. The input lines are saved and unread when the user exits the type-ahead loop with the command \$GO (escape-GO). While in the type-ahead loop, ?? can be used to print the type-ahead, FIX to edit the type-ahead, and \$Q (escape-Q) to erase the last input (may be used repeatedly). The TYPE-AHEAD command may be aborted by \$STOP (escape-STOP); control-E simply aborts the current line of input.

For example:

- ←TYPE-AHEAD
- >SYSOUT(TEM)
- >MAKEFILE(EDIT)
- >BRECOMPILE((EDIT WEDIT))
- >F
- >\$Q
- \\**F**
- >\$Q

\\BRECOMPILE

- >LOAD(WEDIT PROP)
- > BRECOMPILE((EDIT WEDIT))

```
>F
>MAKEFILE(BREAK)
>LISTFILES(EDIT BREAK)
>SYSOUT(CURRENT)
>LOGOUT]
>??
  >SYSOUT(TEM)
  >MAKEFILE(EDIT)
  >LOAD(WEDIT PROP)
  > BRECOMPILE((EDIT WEDIT))
  >F
  >MAKEFILE(BREAK)
  >LISTFILES(EDIT BREAK)
  >SYSOUT(CURRENT)
  >LOGOUT]
>FIX
EDIT
*(R BRECOMPILE BCOMPL)
*P
((LOGOUT) (SYSOUT &) (LISTFILES &) (MAKEFILE &) (F) (BCOMPL
(LOAD &) (MAKEFILE &) (SYSOUT &))
*(DELETE LOAD)
*OK
>$GO
```

Note that type-ahead can be addressed to the compiler, since it uses LISPXREAD for input. Type-ahead can also be directed to the editor, but type-ahead to the editor and to LISPX cannot be intermixed.

The following are some useful functions and variables:

## (VALUEOF LINE)

[NLambda NoSpread Function]

An nlambda function for obtaining the value of a particular event, e.g., (VALUEOF -1), (VALUEOF ←FOO -2). The value of an event consisting of several operations is a list of the values for each of the individual operations.

Note: The value field of a history entry is initialized to bell (control-G). Thus a value of bell indicates that the corresponding operation did not complete, i.e., was aborted or caused an error (or else it returned bell).

Note: Although the input for VALUEOF is entered on the history list before VALUEOF is called, (VALUEOF -1) still refers to the value of the expression immediately before the VALUEOF input, because VALUEOF effectively backs the history list up one entry when it retrieves the specified event. Similarly, (VALUEOF FOO) will find the first event before this one that contains a FOO.

IT [Variable]

The value of the variable IT is always the value of the last event executed, i.e. (VALUEOF -1). For example,

←(SQRT 2)

1.414214

←(SQRTIT)

1.189207

If the last event was a multiple event, e.g. REDO -3 THRU -1, IT is set to value of the last of these events. Following a ?? command, IT is set to value of the last event printed. In other words, in all cases, IT is set to the last value printed on the terminal.

## 13.2.3 P.A. Commands Applied to P.A. Commands

Programmer's assistant commands that unread expressions, such as REDO, USE, etc. do not appear in the input portion of events, although they are stored elsewhere in the event. They do not interfere with or affect the searching operations of event specifications. As a result, p.a. commands themselves cannot be recovered for execution in the normal way. For example, if the user types USE A B C FOR D and follows this with USE E FOR D, he will not produce the effect of USE A B C FOR E, but instead will simply cause E to be substituted for D in the last event containing a D. To produce the desired effect, the user should type USE D FOR E IN USE. The appearance of the word REDO, USE or FIX in an event address specifies a search for the corresponding programmer's assistant command. It also specifies that the text of the programmer's assistant command itself be treated as though it were the input. However, the user must remember that the context in which a history command is reexecuted is that of the current history, not the original context. For example, if the user types USE FOO FOR FIE IN -1, and then later types REDO USE, the -1 will refer to the event before the REDO, not before the USE.

The one exception to the statement that programmer's assistant commands "do not interfere with or affect the searching operations of event specifications" occurs when a p.a. command fails to produce any input. For example, suppose the user types USE LOG FOR ANTILOG AND ANTILOG FOR LOGG, mispelling the second LOG. This will cause an error, LOGG? Since the USE command did not produce any input, the user can repair it by typing USE LOG FOR LOGG, without having to specify IN USE. This latter USE command will invoke a search for LOGG, which will find the bad USE command. The programmer's assistant then performs the indicated substitution, and unreads USE LOG FOR ANTILOG AND ANTILOG FOR LOG. In turn, this USE command invokes a search for ANTILOG, which, because it was

not typed in but reread, ignores the bad **USE** command which was found by the earlier search for **LOGG**, and which is still on the history list. In other words, p.a. commands that fail to produce input are visible to searches arising from event specifications typed in by the user, but not to secondary event specifications.

In addition, if the most recent event is a history command which failed to produce input, a secondary event specification will effectively back up the history list one event so that relative event numbers for that event specification will not count the bad p.a. command. For example, suppose the user types USE LOG FOR ANTILOG AND ANTILOG FOR LOGG IN -2 AND -1, and after the p.a. types LOGG?, the user types USE LOG FOR LOGG. He thus causes the command USE LOG FOR ANTILOG AND ANTILOG FOR LOG IN -2 AND -1 to be constructed and unread. In the normal case, -1 would refer to the last event, i.e., the "bad" USE command, and -2 to the event before it. However, in this case, -1 refers to the event before the bad USE command, and the -2 to the event before that. In short, the caveat above that "the user must remember that the context in which a history command is reexecuted is that of the current history, not the original context" does not apply if the correction is performed immediately.

# 13.3 Changing The Programmer's Assistant

## (CHANGESLICE N HISTORY —)

[Function]

Changes the time-slice of the history list *HISTORY* to *N* (see page 13.31). If *HISTORY* is **NIL**, changes both the top level history list **LISPXHISTORY** and the edit history list **EDITHISTORY**.

Note: The effect of *increasing* the time-slice is gradual: the history list is simply allowed to grow to the corresponding length before any events are forgotten. *Decreasing* the time-slice will immediately remove a sufficient number of the older events to bring the history list down to the proper size. However, **CHANGESLICE** is undoable, so that these events are (temporarily) recoverable. Therefore, if the user wants to recover the storage associated with these events without waiting *N* more events until the **CHANGESLICE** event drops off the history list, he must perform a **FORGET** command (page 13.16).

#### PROMPT#FLG

[Variable]

When this variable is set to T, the current event number to be printed before each prompt character. See PROMPTCHAR, page 13.38. PROMPT#FLG is initially T.

#### **PROMPTCHARFORMS**

[Variable]

The value of **PROMPTCHARFORMS** is a list of expression which are evaluated each time **PROMPTCHAR** (page 13.38) is called to print the prompt character. If **PROMPTCHAR** is going to print something, it first maps down **PROMPTCHARFORMS** evaluating each expression under an **ERRORSET**.

These expressions can access the special variables HISTORY (the current history list), ID (the prompt character to be printed), and PROMPTSTR, which is what PROMPTCHAR will print before ID, if anything. When PROMPT#FLG is T, PROMPTSTR will be the event number. The expressions on PROMPTCHARFORMS can change the shape of a cursor, update a clock, check for mail, etc. or change what PROMPTCHAR is about to print by resetting ID and/or PROMPTSTR. After the expressions on PROMPTCHARFORMS have been evaluated, PROMPTSTR is printed if it is (still) non-NIL, and then ID is printed, if it is (still) non-NIL.

#### **HISTORYSAVEFORMS**

[Variable]

The value of HISTORYSAVEFORMS is a list of expressions that are evaluated under errorset protection each time HISTORYSAVE (page 13.38) creates a new event. This happens each time there is an interaction with the user, but not when performing an operation that is being redone.

The expressions on HISTORYSAVEFORMS are presumably executed for effect, and can access the special variables HISTORY (the current history list), ID (the current prompt character), and EVENT (the current event which HISTORYSAVE is going to return).

Note that **PROMPTCHARFORMS** and **HISTORYSAVEFORMS** together enable bracketing each interaction with the user. These can be used to measure how long the user takes to respond, to use a different readtable or terminal table, etc.

#### **RESETFORMS**

[Variable]

The value of RESETFORMS is a list of forms that are evaluated at each RESET, i.e. when user types control-D, or calls function RESET.

#### **ARCHIVEFN**

[Variable]

If the value of ARCHIVEFN is T, and an event is about to drop off the end of the history list and be forgotten, ARCHIVEFN is called as a function with two arguments: the input portion of the event, and the entire event (see page 13.31 for the format of events). If ARCHIVEFN returns T, the event is archived on a permanent history list (see page 13.16). Note that ARCHIVEFN must be both set and defined. ARCHIVEFN is initially NIL and undefined.

For example, defining ARCHIVEFN as (LAMBDA (X Y) (EQ (CAR X) 'LOAD)) will keep a record of all calls to LOAD.

#### **ARCHIVEFLG**

[Variable]

If the value of ARCHIVEFLG is non-NIL, the system automatically marks all events that are referenced by history commands so that they will be archived when they drop off the history list. ARCHIVEFLG is initially T, so once an event is redone, it is guaranteed to be saved.

An event is "marked for archiving" by putting the property \*ARCHIVE\*, value T, on the event (see page 13.31). The user could do this by means of an appropriately defined LISPXUSERFN (see below).

#### **LISPXMACROS**

[Variable]

LISPXMACROS provides a macro facility that allows the user to define his own programmer's assistant commands. It is a list of elements of the form (COMMAND DEF). Whenever COMMAND appears as the first expression on a line in a LISPX input, the variable LISPXLINE is bound to the rest of the line, the event is recorded on the history list, DEF is evaluated, and DEF's value is stored as the value of the event. Similarly, whenever COMMAND appears as CAR of a form in a LISPX input, the variable LISPXLINE is bound to CDR of the form, the event is recorded, and DEF is evaluated.

An element of the form (COMMAND NIL DEF) is interpreted to mean bind LISPXLINE and evaluate DEF as described above, except do not save the event on the history list.

## LISPXHISTORYMACROS

[Variable]

LISPXHISTORYMACROS allows the user to define programmer's assistant commands that re-execute other events. LISPXHISTORYMACROS is interpreted the same as LISPXMACROS, except that the result of evaluating *DEF* is treated as a list of expressions to be *unread*, exactly as though the expressions had been retrieved by a REDO command, or computed by a USE command. Note that returning NIL means

nothing else is done. This provides a mechanism for defining LISPX commands which are executed for effect only.

Many programmer's assistant commands, such as RETRIEVE, BEFORE, AFTER, etc. are implemented through LISPXMACROS or LISPXHISTORYMACROS.

Note: Definitions of commands on LISPXMACROS or LISPXHISTORYMACROS can be saved on files with the file package command LISPXMACROS (see page 17.39).

#### LISPXUSERFN

[Variable]

When LISPXUSERFN is set to T, it is applied as a function to all inputs not recognized as a programmer's assistant command, or on LISPXMACROS or LISPXHISTORYMACROS. If LISPXUSERFN decides to handle this input, it simply processes it (the event was already stored on the history list before LISPXUSERFN was called), sets LISPXVALUE to the value for the event, and returns T. The programmer's assistant will then know not to call EVAL or APPLY, and will simply store LISPXVALUE into the value slot for the event, and print it. If LISPXUSERFN returns NIL, EVAL or APPLY is called in the usual way. Note that LISPXUSERFN must be both set and defined.

**LISPXUSERFN** is given two arguments: X and LINE. X is the first expression typed, and LINE is the rest of the line, as read by **READLINE** (page 13.36). For example, if the user typed FOO(A B C), X = FOO, and LINE = ((A B C)); if the user typed (FOO A B C), X = FOO and X = FOO a

By appropriately defining (and setting) LISPXUSERFN, the user can with a minimum of effort incorporate the features of the programmer's assistant into his own executive (actually it is the other way around). For example, LISPXUSERFN could be defined to parse all input (other than p.a. commands) in an alternative way. Note that since LISPXUSERFN is called for each input (except for p.a. commands), it can also be used to monitor some condition or gather statistics.

(LISPXPRINT X Y Z NODOFLG)	[Function]
(LISPXPRIN1 X Y Z NODOFLG)	[Function]
(LISPXPRIN2 X Y Z NODOFLG)	[Function]
(LISPXSPACES X Y Z NODOFLG)	[Function]
(LISPXTERPRI X Y Z NODOFLG)	[Function]
(LISPXTAB X Y Z NODOFLG)	[Function]

#### (LISPXPRINTDEF EXPR FILE LEFT DEF TAIL NODOFLG)

[Function]

In addition to saving inputs and values, the programmer's assistant saves most system messages on the history list. For example, FILE CREATED ..., (FN REDEFINED), (VAR RESET), output of TIME, BREAKDOWN, STORAGE, DWIM messages, etc. When ?? prints the event, the output is also printed. This facility is implemented via these functions.

These functions print exactly the same as their non-LISPX counterparts. Then, they put the output on the history list under the property \*LISPXPRINT\* (see page 13.31).

If *NODOFLG* is non-**NIL**, these fuctions do not print, but only put their output on the history list.

To perform output operations from user programs so that the output will appear on the history list, the program needs simply to call the corresponding LISPX printing function.

#### (USERLISPXPRINT X FILE Z NODOFLG)

[Function]

The function **USERLISPXPRINT** is available to permit the user to define additional **LISPX** printing functions. If the user has a function *FN* that takes three or fewer arguments, and the second argument is the file name, he can define a **LISPX** printing function by simply giving **LISPXFN** the definition of **USERLISPXPRINT**, for example, with **MOVD(USERLISPXPRINT LISPXFN)**. **USERLISPXPRINT** is defined to look back on the stack, find the name of the calling function, strip off the leading "**LISPX**", perform the appropriate saving information, and then call the function to do the actual printing.

#### LISPXPRINTFLG

[Variable]

If LISPXPRINTFLG = NIL, the LISPX printing functions will not store their output on the history list. LISPXPRINTFLG is initially T.

## 13.4 Undoing

Note: This discussion only applies to undoing under the executive and break; the editors handles undoing itself in a slightly different fashion.

The UNDO capability of the programmer's assistant is implemented by requiring that each operation that is to be undoable be responsible itself for saving on the history list enough information to enable reversal of its side effects. In other words, the assistant does not "know" when it is about to perform a destructive operation, i.e., it is not constantly checking or anticipating. Instead, it simply executes operations, and any undoable changes that occur are automatically saved on the history list by the responsible functions. The UNDO command, which involves recovering the saved information and performing the corresponding inverses, works the same way, so that the user can UNDO an UNDO, and UNDO that etc.

At each point, until the user specifically requests an operation to be undone, the assistant does not know, or care, whether information has been saved to enable the undoing. Only when the user attempts to undo an operation does the assistant check to see whether any information has been saved. If none has been saved, and the user has specifically named the event he wants undone, the assistant types nothing saved. (When the user simply types UNDO, the assistant searches for the last undoable event, ignoring events already undone as well as UNDO operations themselves.)

This implementation minimizes the overhead for undoing. Only those operations which actually make changes are affected, and the overhead is small: two or three cells of storage for saving the information, and an extra function call. However, even this small price may be too expensive if the operation is sufficiently primitive and repetitive, i.e., if the extra overhead may seriously degrade the overall performance of the program. Hence not every destructive operation in a program should necessarily be undoable; the programmer must be allowed to decide each case individually.

Therefore for each primitive destructive function, Interlisp has defined an undoable version which always saves information. By convention, the name of the undoable version of a function is the function name, preceded by "/." For example, there is RPLACA and /RPLACA, REMPROP and /REMPROP, etc. The "slash" functions that are currently implemented can be found as the value of /FNS.

The various system packages use the appropriate undoable functions. For example, BREAK uses /PUTD and /REMPROP so as to be undoable, and DWIM uses /RPLACA and /RPLACD, when it makes a correction. Similarly, the user can simply use the

corresponding / function if he wants to make a destructive operation in his own program undoable. When the / function is called, it will save the UNDO information in the current event on the history list.

The effects of the following functions are always undoable: DEFINE, DEFINEQ, DEFC (used to give a function a compiled code definition), DEFLIST, LOAD, SAVEDEF, UNSAVEDEF, BREAK, UNBREAK, REBREAK, TRACE, BREAKIN, UNBREAKIN, CHANGENAME, EDITFNS, EDITF, EDITV, EDITP, EDITE, EDITL, ESUBST, ADVISE, UNADVISE, READVISE, plus any changes caused by DWIM.

The programmer's assistant cannot know whether efficiency and overhead are serious considerations for the execution of an expression in a user program, so the user must decide if he wants these operations undoable by explicitly calling /MAPCONC, etc. However, typed-in expressions rarely involve iterations or lengthy computations directly. Therefore, before evaluating the user input, the programmer's assistant substitutes the corresponding undoable function for any destructive function (using LISPX/, page 13.41). For example, if the user types (MAPCONC NASDIC ...), it is actually (/MAPCONC NASDIC ...) that is evaluated. Obviously, with a more sophisticated analysis of both user input and user programs, the decision concerning which operations to make undoable could be better advised. However, we have found the configuration described here to be a very satisfactory one. The user pays a very small price for being able to undo what he types in, and if he wishes to protect himself from malfunctioning in his own programs, he can have his program explicitly call undoable functions.

Note: The user can define new "slash" functions to be translated on type-in by calling **NEW/FN** (page 13.41).

# 13.4.1 Undoing Out of Order

/RPLACA operates undoably by saving (on the history list) the list cell that is to be changed and its original CAR. Undoing a /RPLACA simply restores the saved CAR. This implementation can produce unexpected results when multiple /RPLACAs are done on the same list cell, and then undone out of order. For example, if the user types (RPLACA FOO 1), followed by (RPLACA FOO 2), then undoes both events by undoing the most recent event first, then undoing the older event, FOO will be restored to its state before either RPLACA operated. However if the user undoes the first event, then the second event, (CAR FOO) will be 1, since this is what was in CAR of FOO before (RPLACA FOO 2) was executed. Similarly, if the user types (NCONC1 FOO 1), followed by (NCONC1 FOO 2), undoing just (NCONC1 FOO 1) will remove

INTERLISP EXECUTIVE

both 1 and 2 from FOO. The problem in both cases is that the two operations are not "independent." In general, operations are always independent if they affect different lists or different sublists of the same list. Undoing in reverse order of execution, or undoing independent operations, is always guaranteed to do the "right" thing. However, undoing dependent operations out of order may not always have the predicted effect.

Property list operations, (i.e., PUTPROP, ADDPROP and REMPROP) are handled specially, so that operations that affect different properties on the same property list are always independent. For example, if the user types (PUTPROP 'FOO 'BAR 1) then (PUTPROP 'FOO 'BAZ 2), then undoes the first event, the BAZ property will remain, even though it may not have been on the property list of FOO at the time the first event was executed.

#### **13.4.2 SAVESET**

Typed-in SETs are made undoable by substituting a call to SAVESET. SETQ is made undoable by substituting SAVESETQ, and SETQQ by SAVESETQQ, both of which are implemented in terms of SAVESET.

In addition to saving enough information on the history list to enable undoing, SAVESET operates in a manner analogous to SAVEDEF (page 17.27) when it resets a top level value: when it changes a top level binding from a value other than NOBIND to a new value that is not EQUAL to the old one, SAVESET saves the old value of the variable being set on the variable's property list under the property VALUE, and prints the message (VARIABLE RESET). The old value can be restored via the function UNSET, which also saves the current value (but does not print a message). Thus UNSET can be used to flip back and forth between two values.

Of course, UNDO can be used as long as the event containing this call to SAVESET is still active. Note however that the old value will remain on the property list, and therefore be recoverable via UNSET, even after the original event has been forgotten.

**RPAQ** and **RPAQQ** are implemented via calls to **SAVESET**. Thus old values will be saved and messages printed for any variables that are reset as the result of loading a file.

For top level variables, SAVESET also adds the variable to the appropriate spelling list, thereby noticing variables set in files via RPAQ or RPAQQ, as well as those set via type-in.

#### (SAVESET NAME VALUE TOPFLG FLG)

[Function]

An undoable SET. SAVESET scans the stack looking for the last binding of NAME, sets NAME to VALUE, and returns VALUE.

If the binding changed was a top level binding, *NAME* is added to the spelling list **SPELLINGS3** (see page 20.17). Furthermore, if the old value was not **NOBIND**, and was also not **EQUAL** to the new value, **SAVESET** calls the file package to update the necessary file records. Then, if **DFNFLG** is not equal to **T**, **SAVESET** prints (*NAME* RESET), and saves the old value on the property list of *NAME*, under the property **VALUE**.

If *TOPFLG* = T, SAVESET operates as above except that it always uses *NAME*'s top-level value cell. When *TOPFLG* is T, and **DFNFLG** is **ALLPROP** and the old value was not **NOBIND**, SAVESET simply stores *VALUE* on the property list of *NAME* under the property **VALUE**, and returns *VALUE*. This option is used for loading files without disturbing the current value of variables (see page 10.10).

If *FLG* = **NOPRINT**, **SAVESET** saves the old value, but does not print the message. This option is used by **UNSET**.

If FLG = NOSAVE, SAVESET does not save the old value on the property list, nor does it add NAME to SPELLINGS3. However, the call to SAVESET is still undoable. This option is used by /SET.

If FLG=NOSTACKUNDO, SAVESET is undoable only if the binding being changed is a top-level binding, i.e. this says when resetting a variable that has been rebound, don't bother to make it undoable.

(UNSET NAME)

[Function]

If *NAME* does not contain a property VALUE, UNSET generates an error. Otherwise UNSET calls SAVESET with *NAME*, the property value, *TOPFLG* = T, and *FLG* = NOPRINT.

# 13.4.3 UNDONLSETQ and RESETUNDO

The function **UNDONLSETQ** provides a limited form of backtracking: if an error occurs under the **UNDONLSETQ**, all undoable side effects executed under the **UNDONLSETQ** are undone. **RESETUNDO**, used in conjunction with **RESETLST** and **RESETSAVE** (page 14.24), provides a more general undo capability where the user can specify that the side effects be undone after the specified computation finishes, is aborted by an error, or by a control-D.

## (UNDONLSETQ UNDOFORM —)

[NLambda Function]

An nlambda function similar to NLSETQ (page 14.22). UNDONLSETQ evaluates UNDOFORM, and if no error occurs during the evaluation, returns (LIST (EVAL UNDOFORM)) and passes the undo information from UNDOFORM (if any) upwards. If an error does occur, the UNDONLSETQ returns NIL, and any undoable changes made during the evaluation of UNDOFORM are undone.

Any undo information is stored directly on the history event (if LISPXHIST is not NIL), so that if the user control-D's out of the UNDONLSETQ, the event is still undoable.

**UNDONLSETQ** will operate correctly if **#UNDOSAVES** is or has been exceeded for this event, or is exceeded while under the scope of the **UNDONLSETQ**.

Note: Caution must be exercised in using coroutines or other non-standard means of exiting while under an UNDONLSETQ. See discussion in page 14.24.

#### (RESETUNDO X STOPFLG)

[Function]

For use in conjunction with RESETLST (page 14.24). (RESETUNDO) initializes the saving of undo information and returns a value which when given back to RESETUNDO undoes the intervening side effects. For example, (RESETLST (RESETSAVE (RESETUNDO)) . FORMS) will undo the side effects of FORMS on normal exit, or if an error occurs or a control-D is typed.

If STOPFLG = T, RESETUNDO stops accumulating undo information it is saving on X. Note that this has no bearing on the saving of undo information on higher RESETUNDO's, or on being able to undo the entire event.

For example,

(RESETLST
(SETQ FOO (RESETUNDO))
(RESETSAVE NIL (LIST 'RESETUNDO FOO))
(ADVISE ...)
(RESETUNDO FOO T)
. FORMS)

would cause the advice to be undone, but *not* any of the side effects in *FORMS*.

# 13.5 Format and Use of the History List

The system currently uses three history lists, LISPXHISTORY for the top-level Interlisp executive, EDITHISTORY for the editors, and ARCHIVELST for archiving events (see page 13.16). All history lists have the same format, use the same functions, HISTORYSAVE, for recording events, and use the same set of functions for implementing commands that refer to the history list, e.g., HISTORYFIND, PRINTHISTORY, UNDOSAVE, etc.

Each history list is a list of the form (*L EVENT# SIZE MOD*), where *L* is the list of events with the most recent event first, *EVENT#* is the event number for the most recent event on *L*, *SIZE* is the size of the time-slice (below), i.e., the maximum length of *L*, and *MOD* is the highest possible event number. **LISPXHISTORY** and **EDITHISTORY** are both initialized to (NIL 0 100 100). Setting **LISPXHISTORY** or **EDITHISTORY** to NIL disables all history features, so **LISPXHISTORY** and **EDITHISTORY** act like flags as well as repositories of events.

Note: One of the reasons why users may disable the history list facility is to allow the garbage collector to reclaim objects stored on the history list. Simply setting LISPXHISTORY to NIL will not necessarily remove all pointers to the history list. GAINSPACE (page 22.12) is a useful function when trying to reclaim memory space.

Each history list has a maximum length, called its "time-slice." As new events occur, existing events are aged, and the oldest events are "forgotten." For efficiency, the storage used to represent the forgotten event is reused in the representation of the new event, so the history list is actually a ring buffer. The time-slice of a history list can be changed with the function CHANGESLICE (page 13.21). Larger time-slices enable longer "memory spans," but tie up correspondingly greater amounts of storage. Since the user seldom needs really "ancient history," and a facility is provided for saving and remembering selected events (see NAME and RETRIEVE, page 13.14), a relatively small time-slice such as 30 events is more than adequate, although some users prefer to set the time-slice as large as 100 events.

If **PROMPT#FLG** (page 13.22) is set to **T**, an "event number" will be printed before each prompt. More recent events have higher numbers. When the event number of the current event is 100, the next event will be given number 1. If the time-slice is greater than 100, the "roll-over" occurs at the next highest hundred, so that at no time will two events ever have the same event number. For example, if the time-slice is 150, event number 1 will follow event number 200.

Each individual event on L is a list of the form (INPUT ID VALUE. PROPS). ID is the prompt character for this event, e.g.,  $\leftarrow$ , :,  $\star$ , etc. VALUE is the value of the event, and is initialized to bell. On

**EDITHISTORY**, this field is used to save the side effects of each command (see page 13.43). *PROPS* is a property list used to associate other information with the event (described below).

INPUT is the input sequence for the event. Normally, this is just the input that the user typed-in. For an APPLY-format input (see page 13.4), this is a list consisting of two expressions; for an EVAL-format input, this is a list of just one expression; for an input entered as list of atoms, INPUT is simply that list. For example,

User Input INPUT is:

PLUS[1 1] (PLUS (1 1))

(PLUS 1 1) ((PLUS 1 1))

PLUS 1 1<sup>cr</sup> (PLUS 1 1)

If the user types in a programmer's assistant command that "unreads" and reexecutes other events (REDO, USE,, etc.), INPUT contains a "sequence" of the inputs from the redone events. Specifically, the INPUT fields from the specified events are concatenated into a single list, seperated by special markers called "pseudo-carriage returns," which print out as the string "<c.r.>". When the result of this concatenation is "reread," the pseudo-carriage-returns are treated by LISPXREAD and READLINE exactly as real carriage returns, i.e., they serve to distinguish between APPLY-format and EVAL-format inputs to LISPX, and to delimit line commands to the editor.

Note: The value of the variable HISTSTR0 is used to represent a pseudo-carriage return. This is initially the string "<c.r.>". Note that the functions that recognize pseudo-carriage returns compare them to HISTSTR0 using EQ, so this marker will never be confused with a string that was typed in by the user.

The same convention is used for representing multiple inputs when a USE command involves sequential substitutions. For example, if the user types GETD(FOO) and then USE FIE FUM FOR FOO, the input sequence that will be constructed is (GETD (FIE) "<c.r.>" GETD (FUM)), which is the result of substituting FIE for FOO in (GETD (FOO)) concatenated with the result of substituting FUM for FOO in (GETD (FOO)).

Note that once a multiple input has been entered as the input portion of a new event, that event can be treated exactly the same as one resulting from type-in. In other words, no special checks have to be made when referencing an event, to see if it is simple or multiple. This implementation permits an event specification to refer to a single simple event, or to several events, or to a single event originally constructed from several events (which may themselves have been multiple input events, etc.) without having to treat each case separately.

REDO, RETRY, USE, ..., and FIX commands, i.e., those commands that reexecute previous events, are not stored as inputs, because the input portion for these events are the expressions to be "reread". The history commands UNDO, NAME, RETRIEVE, BEFORE, and AFTER are recorded as inputs, and ?? prints them exactly as they were typed.

PROPS is a property list of the form (PROPERTY<sub>1</sub> VALUE<sub>1</sub> PROPERTY<sub>2</sub> VALUE<sub>2</sub> ...), that can be used to associate arbitrary information with a particular event. Currently, the following properties are used by the programmer's assistant:

SIDE A list of the side effects of the event. See UNDOSAVE, page 13.40.

\*PRINT\* Used by the ?? command when special formatting is required, for example, when printing events corresponding to the break commands OK, GO, EVAL, and ? = .

**USE-ARGS** 

...ARGS

The **USE-ARGS** and **...ARGS** properties are used to save the arguments and expression for the corresponding history command.

\*ERROR\*

\*CONTEXT\* \*ERROR\* and \*CONTEXT\* are used to save information when errors occur for subsequent use by the \$ command. Whenever an error occurs, the offender is automatically saved on that event's entry in the history list, under the \*ERROR\* property.

\*LISPXPRINT\* Used to record calls to LISPXPRINT, LISPXPRIN1, etc. (see page 13.25).

\*ARCHIVE\* The property \*ARCHIVE\* on an event causes the event to be automatically archived when it "falls off the end" of the history list (see page 13.16).

\*GROUP\*

\*HISTORY\* The \*HISTORY\* and \*GROUP\* properties are used for commands that reexecute previous events, i.e., REDO, RETRY, USE, ..., and FIX. The value of the \*HISTORY\* property is the history command that the user actually typed, e.g., REDO FROM F. This is used by the ?? command when printing the event. The value of the \*GROUP\* property is a structure containing the side effects, etc. for the individual inputs being reexecuted. This

structure is described below.

When LISPX is given an input, it calls HISTORYSAVE (page 13.38) to record the input in a new event (except for the commands ??, FORGET, TYPE-AHEAD, \$BUFS, and ARCHIVE, that are executed immediately and are not recorded on the history list). Normally, HISTORYSAVE creates and returns a new event. LISPX binds the variable LISPXHIST to the value of HISTORYSAVE, so that when the operation has completed, LISPX knows where to store the value. Note that by the time it completes, the operation may no

longer correspond to the most recent event on the history list. For example, all inputs typed to a lower break will appear later on the history list. After binding LISPXHIST, LISPX executes the input, stores its value in the value field of the LISPXHIST event, prints the value, and returns.

When the input is a REDO, RETRY, USE, ..., or FIX command, the procedure is similar, except that the event is also given a \*GROUP\* property, initially NIL, and a \*HISTORY\* property, and LISPX simply unreads the input and returns. When the input is "reread", it is HISTORYSAVE, not LISPX, that notices this fact, and finds the event from which the input originally came. If HISTORYSAVE cannot find the event, for example if a user program unreads the input directly, and not via a history command, HISTORYSAVE proceeds as though the input were typed. HISTORYSAVE then adds a new (INPUT ID VALUE . PROPS) entry to the \*GROUP\* property for this event, and returns this entry as the "new event." LISPX then proceeds exactly as when its input was typed directly, i.e., it binds LISPXHIST to the value of HISTORYSAVE, executes the input, stores the value in CADDR of LISPXHIST, prints the value, and returns. In fact, LISPX never notices whether it is working on freshly typed input, or input that was reread. Similarly, UNDOSAVE will store undo information on LISPXHIST the same as always, and does not know or care that LISPXHIST is not the entire event, but one of the elements of the \*GROUP\* property. Thus when the event is finished, its entry will look like:

```
(INPUT ID VALUE

*HISTORY*

COMMAND

*GROUP*

((INPUT<sub>1</sub> ID<sub>1</sub> VALUE<sub>1</sub> SIDE SIDE<sub>1</sub>)

(INPUT<sub>2</sub> ID<sub>2</sub> VALUE<sub>2</sub> SIDE SIDE<sub>2</sub>)
...))
```

In this case, the value field of the event with the \*GROUP\* property is not being used; VALUEOF instead returns a list of the values from the \*GROUP\* property. Similarly, UNDO operates by collecting the SIDE properties from each of the elements of the \*GROUP\* property, and then undoing them in reverse order.

This implementation removes the burden from the function calling HISTORYSAVE of distinguishing between new input and reexecution of input whose history entry has already been set up.

# 13.6 Programmer's Assistant Functions

# (LISPX LISPXX LISPXID LISPXXMACROS LISPXXUSERFN LISPXFLG)

[Function]

LISPX is the primary function of the programmer's assistant. LISPX takes one user input, saves it on the history list, evaluates it, saves its value, and prints and returns it. LISPX also interpretes p.a. commands, LISPXMACROS, LISPXHISTORYMACROS, and LISPXUSERFN.

If LISPXX is a list, it is interpreted as the input expression. Otherwise, LISPX calls READLINE, and uses LISPXX plus the value of READLINE as the input for the event. If LISPXX is a list CAR of which is LAMBDA or NLAMBDA, LISPX calls LISPXREAD to obtain the arguments.

LISPXID is the prompt character to print before accepting user input. The user should be careful about using the prompt characters "\(\Lipsi\)," "\*," or ":," because in certain cases LISPX uses the value of LISPXID to tell whether or not it was called from the break package or editor.

If LISPXXMACROS is not NIL, it is used as the list of LISPX macros, otherwise the top level value of the variable LISPXMACROS is used.

If LISPXXUSERFN is not NIL, it is used as the LISPXUSERFN. In this case, it is not necessary to both set and define LISPXUSERFN as described on page 13.24.

LISPXFLG is used by the E command in the editor (see page 13.43).

Note that the history is *not* one of the arguments to LISPX, i.e., the editor must bind (reset) LISPXHISTORY to EDITHISTORY before calling LISPX to carry out a history command. LISPX will continue to operate as an EVAL/APPLY function if LISPXHISTORY is **NIL**. Only those functions and commands that involve the history list will be affected.

LISPX performs spelling corrections using LISPXCOMS, a list of its commands, as a spelling list whenever it is given an unbound atom or undefined function, before attempting to evaluate the input.

**LISPX** is responsible for rebinding **HELPCLOCK**, used by **BREAKCHECK** (page 14.13) for computing the amount of time spent in a computation, in order to determine whether to go into a break if and when an error occurs.

#### (USEREXEC LISPXID LISPXXMACROS LISPXXUSERFN)

[Function]

Repeatedly calls LISPX under errorset protection specifying LISPXXMACROS and LISPXXUSERFN, and using LISPXID (or  $\leftarrow$  if

LISPXID = NIL) as a prompt character. USEREXEC is exited via the command OK, or else with a RETFROM.

#### (LISPXEVAL LISPXFORM LISPXID)

[Function]

Evaluates *LISPXFORM* (using EVAL) the same as though it were typed in to *LISPX*, i.e., the event is recorded, and the evaluation is made undoable by substituting the slash functions for the corresponding destructive functions (see page 13.27). *LISPXEVAL* returns the value of the form, but does not print it.

When LISPX recieves an "input," it may come from the user typing it in, or it may be an input that has been "unread." LISPX handles these two cases by getting inputs with LISPXREAD and READLINE, described below. These functions use the following variable to store the expressions that have been unread:

#### **READBUF**

[Variable]

This variable is used by LISPXREAD and READLINE to store the expressions that have been unread. When READBUF is not NIL, READLINE and LISPXREAD "read" expressions from READBUF until READBUF is NIL, or until they read a pseudo-carriage return (see page 13.32). Both functions return a list of the expressions that have been "read." (The pseudo-carriage return is not included in the list.)

When READBUF is NIL, both LISPXREAD and READLINE actually obtain their input by performing (APPLY\* LISPXREADFN FILE), where LISPXREADFN is initially set to TTYINREAD (page 26.28). The user can make LISPX, the editor, break, etc. do their reading via a different input function by simply setting LISPXREADFN to the name of that function (or an appropriate LAMBDA expression).

Note: The user should only add expressions to READBUF using the function LISPXUNREAD (page 13.38), which knows about the format of READBUF.

# (READLINE RDTBL — —)

[Function]

Reads a line from the terminal, returning it as a list. If (READP T) is NIL, READLINE returns NIL. Otherwise it reads expressions until it encounters either:

 an EOL (typed by the user) that is not preceded by any spaces, e.g.,

# A B CCr

and READLINE returns (A B C)

 a list terminating in a "]", in which case the list is included in the value of READLINE, e.g.,

#### AB(CD)

# and READLINE returns (A B (C D)).

 an unmatched right parentheses or right square bracket, which is not included in the value of READLINE, e.g.,

#### ABC]

and READLINE returns (A B C).

In the case that one or more spaces precede a carriage-return, or a list is terminated with a ")", **READLINE** will type "..." and continue reading on the next line, e.g.,

# A B CCr

...(D E F)

...(X Y Z]

and READLINE returns (A B C (D E F) (X Y Z)).

If the user types another carriage-return after the "...", the line will terminate, e.g.,

# A B CCr

\_\_cr

and READLINE returns (A B C).

Note that carriage-return, i.e., the **EOL** character, can be redefined with **SETSYNTAX** (page 25.37). **READLINE** actually checks for the **EOL** character, whatever that may be. The same is true for right parenthesis and right bracket.

When READLINE is called from LISPX, it operates differently in two respects:

- (1) If the line consists of a single ) or ], READLINE returns (NIL) instead of NIL, i.e., the ) or ] is included in the line. This permits the user to type FOO) or FOO], meaning call the function FOO with no arguments, as opposed to FOO<sup>CT</sup> (FOO<carriage-return>), meaning evaluate the variable FOO.
- (2) If the first expression on the line is a list that is not preceded by any spaces, the list terminates the line regardless of whether or not it is terminated by ]. This permits the user to type EDITF(FOO) as a single input.

Note that if any spaces are inserted between the atom and the left parentheses or bracket, **READLINE** will assume that the list does not terminate the line. This is to enable the user to type a line command such as **USE (FOO) FOR FOO**. Therefore, in the user accidentially puts an extra space between a function and its arguments, the will have to complete the input with another carriage return, e.g.,

# ←EDITF (FOO)

...cr

#### **EDIT**

.

Note: READLINE reads expressions by performing (APPLY\* LISPXREADFN T). LISPXREADFN (page 13.36) is initially set to TTYINREAD (page 26.28).

#### (LISPXREAD FILE RDTBL)

[Function]

A generalized READ. If READBUF = NIL, LISPXREAD performs (APPLY\* LISPXREADFN FILE), which it returns as its value. If READBUF is not NIL, LISPXREAD "reads" and returns the next expression on READBUF.

LISPXREAD also sets REREADFLG (page 13.39) to NIL when it reads via LISPXREADFN, and sets REREADFLG to the value of READBUF when rereading.

# (LISPXREADP FLG)

[Function]

A generalized READP. If FLG = T, LISPXREADP returns T if there is any input waiting to be "read", in the manner of LISPXREAD. If FLG = NIL, LISPXREADP returns T only if there is any input waiting to be "read" on this line. In both cases, leading spaces are ignored, i.e., skipped over with READC, so that if only spaces have been typed, LISPXREADP will return NIL.

#### (LISPXUNREAD LST ---)

[Function]

Unreads LST, a list of expressions.

#### (PROMPTCHAR ID FLG HISTORY)

[Function]

Called by LISPX to print the prompt character *ID* before each input. **PROMPTCHAR** will not print anything when the next input will be "reread", i.e., when **READBUF** is not **NIL**.

**PROMPTCHAR** will not print when (READP) = T, unless FLG is T. The editor calls **PROMPTCHAR** with FLG = **NIL** so that extra \*'s are not printed when the user types several commands on one line. However, **EVALQT** calls **PROMPTCHAR** with FLG = T, since it always wants the  $\leftarrow$  printed (except when "rereading").

If **PROMPT#FLG** (page 13.22) is **T** and *HISTORY* is not **NIL**, **PROMPTCHAR** prints the current event number (of *HISTORY*) before printing *ID*.

The value of **PROMPTCHARFORMS** (page 13.22) is a list of expressions that are evaluated by **PROMPTCHAR** before, and if, it does any printing.

## (HISTORYSAVE HISTORY ID INPUT1 INPUT2 INPUT3 PROPS)

[Function]

Records one event on HISTORY.

If INPUT1 is not NIL, the input is of the form  $(INPUT_1 \ INPUT_2 \ .$   $INPUT_3)$ . If  $INPUT_1$  is NIL, and  $INPUT_2$  is not NIL, the input is of the form  $(INPUT_2 \ . \ INPUT_3)$ . Otherwise, the input is just  $INPUT_3$ .

**HISTORYSAVE** creates a new event with the corresponding input, *ID*, value field initialized to bell, and *PROPS*. If the *HISTORY* has reached its full size, the last event is removed and cannibalized.

The value of HISTORYSAVE is the new event. However, if REREADFLG is not NIL, and the most recent event on the history list contains the history command that produced this input, HISTORYSAVE does not create a new event, but simply adds an (INPUT ID bell . PROPS) entry to the \*GROUP\* property for that event and returns that entry. See discussion on page 13.34.

HISTORYSAVEFORMS (page 13.22) is a list of expressions that are evaluated under errorset protection each time HISTORYSAVE creates a new event.

## (LISPXSTOREVALUE EVENT VALUE)

[Function]

Used by LISPX for storing the value of an event. Can be advised by user to watch for particular values or perform other monitoring functions.

#### (LISPXFIND HISTORY LINE TYPE BACKUP —)

[Function]

LINE is an event specification, TYPE specifies the format of the value to be returned by LISPXFIND, and can be either ENTRY, ENTRIES, COPY, COPIES, INPUT, or REDO. LISPXFIND parses LINE, and uses HISTORYFIND (page 13.40) to find the corresponding events. LISPXFIND then assembles and returns the appropriate structure.

**LISPXFIND** incorporates the following special features:

- (1) if BACKUP = T, LISPXFIND interprets LINE in the context of the history list before the current event was added. This feature is used, for example, by VALUEOF, so that (VALUEOF -1) will not refer to the VALUEOF event itself.
- (2) if LINE = NIL and the last event is an UNDO, the next to the last event is taken. This permits the user to type UNDO followed by REDO or USE.
- (3) LISPXFIND recognizes @@, and searches the archived history list instead of *HISTORY* (see the ARCHIVE command, page 13.16).
- (4) LISPXFIND recognizes @, and retrieves the corresponding event(s) from the property list of the atom following @ (see page 13.14).

#### (HISTORYFIND LST INDEX MOD EVENTADDRESS —)

[Function]

Searches LST and returns the tails of LST beginning with the event corresponding to EVENTADDRESS. LST, INDEX, and MOD are the first three elements of a "history list" structure (see page 13.31). EVENTADDRESS is an event address (see page 13.6) e.g., (43), (-1), (FOO FIE), (LOAD ← FOO), etc. If HISTORYFIND cannot find EVENTADDRESS, it generates an error.

#### (HISTORYMATCH INPUT PAT EVENT)

[Function]

Used by **HISTORYFIND** for "matching" when *EVENTADDRESS* specifies a pattern. Matches *PAT* against *INPUT*, the input portion of the history event *EVENT*, as matching is defined on page 16.18. Initially defined as **(EDITFINDP INPUT PAT T)**, but can be advised or redefined by the user.

## (ENTRY# HIST X)

[Function]

HIST is a history list (see page 13.31). X is EQ to one of the events on HIST. ENTRY# returns the event number for X.

#### (UNDOSAVE UNDOFORM HISTENTRY)

[Function]

**UNDOSAVE** adds the "undo information" *UNDOFORM* to the **SIDE** property of the history event *HISTENTRY*. If there is no **SIDE** property, one is created. If the value of the **SIDE** property is **NOSAVE**, the information is not saved.

HISTENTRY specifies an event. If HISTENTRY = NIL, the value of LISPXHIST is used. If both HISTENTRY and LISPXHIST are NIL, UNDOSAVE is a no-op. Note that HISTENTRY (or LISPXHIST) can either be a "real" event, or an event within the \*GROUP\* property of another event (see page 13.34).

The form of *UNDOFORM* is (FN . ARGS). Undoing is done by performing (APPLY (CAR *UNDOFORM*) (CDR *UNDOFORM*)). For example, if the definition of FOO is *DEF*, (/PUTD FOO *NEWDEF*) will cause a call to **UNDOSAVE** with *UNDOFORM* = (/PUTD FOO *DEF*).

Note: In the special case of /RPLNODE and /RPLNODE2, the format of *UNDOFORM* is (*X OLDCAR . OLDCDR*). When *UNDOFORM* is undone, this form is recognized and handled specially. This implementation saves space.

CAR of the SIDE property of an event is a count of the number of *UNDOFORMs* saved for this event. Each call to *UNDOSAVE* increments this count. If this count is set to -1, then it is never incremented, and any number of *UNDOFORMs* can be saved. If this count is a positive number, *UNDOSAVE* restricts the number of *UNDOFORMs* saved to the value of #UNDOSAVES, described below. LOAD initializes the count to -1, so that regardless of the

value of #UNDOSAVES, no message will be printed, and the LOAD will be undoable.

#### **#UNDOSAVES**

[Variable]

The value of #UNDOSAVES is the maximum number of UNDOFORMs to be saved for a single event. When the count of UNDOFORMs reaches this number, UNDOSAVE prints the message CONTINUE SAVING?, asking the user if he wants to continue saving. If the user answers NO or defaults, UNDOSAVE discards the previously saved information for this event, and makes NOSAVE be the value of the property SIDE, which disables any further saving for this event. If the user answers YES, UNDOSAVE changes the count to -1, which is then never incremented, and continues saving. The purpose of this feature is to avoid tying up large quantities of storage for operations that will never need to be undone.

If #UNDOSAVES is negative, then when the count reaches -#UNDOSAVES, UNDOSAVE simply stops saving without printing any messages or interacting with the user. #UNDOSAVES = NIL is equivalent to #UNDOSAVES = infinity. #UNDOSAVES is initially NIL.

### (NEW/FN FN)

[Function]

**NEW/FN** performs the necessary housekeeping operations to make *FN* be translated to the undoable version */FN* when typed-in. For example, **RADIX** can be made undoable when typed-in by performing:

← (DEFINEQ (/RADIX (X)

(UNDOSAVE (LIST '/RADIX (RADIX X))
(/RADIX)

← (NEW/FN 'RADIX)

# (LISPX/ X FN VARS)

[Function]

**LISPX**/ performs the substitution of / functions for destructive functions that are typed-in. If *FN* is not **NIL**, it is the name of a function, and *X* is its argument list. If *FN* is **NIL**, *X* is a form. In both cases, **LISPX**/ returns *X* with the appropriate substitutions. *VARS* is a list of bound variables (optional).

LISPX/ incorporates information about the syntax and semantics of Interlisp expressions. For example, it does not bother to make undoable operations involving variables bound in X. It does not perform substitution inside of expressions CAR of which is an nlambda function (unless CAR of the form has the property INFO value EVAL, see page 21.21). For example, (BREAK PUTD) typed to LISPX, will break on PUTD, not /PUTD. Similarly, substitution should be performed in the arguments for functions like MAPC, RPTQ, etc., since these contain expressions that will be evaluated

or applied. For example, if the user types (MAPC '(FOO1 FOO2 FOO3) 'PUTD) the PUTD must be replaced by /PUTD.

# (UNDOLISPX LINE)

[Function]

LINE is an event specification. UNDOLISPX is the function that executes UNDO commands by calling UNDOLISPX1 on the appropriate entry(s).

## (UNDOLISPX1 EVENT FLG —)

[Function]

Undoes one event. UNDOLISPX1 returns NIL if there is nothing to be undone. If the event is already undone, UNDOLISPX1 prints already undone and returns T. Otherwise, UNDOLISPX1 undoes the event, prints a message, e.g., SETQ undone, and returns T.

If FLG=T and the event is already undone, or is an undo command, UNDOLISPX1 takes no action and returns NIL. UNDOLISPX uses this option to search for the last event to undo. Thus when LINE = NIL, UNDOLISPX simply searches history until it finds an event for which UNDOLISPX1 returns T.

Undoing an event consists of mapping down (CDR of) the property value for SIDE, and for each element, applying CAR to CDR, and then marking the event undone by attaching (with /ATTACH) a NIL to the front of its SIDE property. Note that the undoing of each element on the SIDE property will usually cause undosaves to be added to the *current* LISPXHIST, thereby enabling the effects of UNDOLISPX1 to be undone.

## (PRINTHISTORY HISTORY LINE SKIPFN NOVALUES FILE)

[Function]

LINE is an event specification. PRINTHISTORY prints the events on HISTORY specified by LINE, e.g., (-1 THRU -10). Printing is performed via the function SHOWPRIN2, so that if the value of SYSPRETTYFLG = T, events will be prettyprinted.

SKIPFN is an (optional) functional argument that is applied to each event before printing. If it returns non-NIL, the event is skipped, i.e., not printed.

If NOVALUES = T, or NOVALUES applied to the corresponding event is true, the value is not printed. For example, NOVALUES is T when printing events on EDITHISTORY.

For example, the following LISPXMACRO will define ??' as a command for printing the history list while skipping all "large events" and not printing any values.

(??' (PRINTHISTORY
LISPXHISTORY
LISPXLINE
(FUNCTION (LAMBDA (X)

# (IGREATERP (COUNT (CAR X)) 5)))

T

T))

# 13.7 The Editor and the Programmer's Assistant

As mentioned earlier, all of the remarks concerning "the programmer's assistant" apply equally well to user interactions with EVALQT, BREAK or the editor. The differences between the editor's implementation of these features and that of LISPX are mostly obvious or inconsequential. However, for completeness, this section discusses the editor's implementation of the programmer's assistant.

The editor uses PROMPTCHAR to print its prompt character, and LISPXREAD, LISPXREADP, and READLINE for obtaining inputs. When the editor is given an input, it calls HISTORYSAVE to record the input in a new event on its history list, EDITHISTORY, except that the atomic commands OK, STOP, SAVE, P, ?, PP and E are not recorded. In addition, number commands are grouped together in a single event. For example, 3 3 -1 is considered as one command for changing position. EDITHISTORY follows the same conventions and format as LISPXHISTORY (page 13.31). However, since edit commands have no value, the editor uses the value field for saving side effects, rather than storing them under the property SIDE.

The editor recognizes and processes the four commands DO, !E, !F, and !N which refer to previous events on EDITHISTORY. The editor also processes UNDO itself, as described below. All other history commands are simply given to LISPX for execution, after first binding (resetting) LISPXHISTORY to EDITHISTORY. The editor also calls LISPX when given an E command (page 16.57). In this case, the editor uses the fifth argument to LISPX, LISPXFLG, to specify that any history commands are to be executed by a recursive call to LISPX, rather than by unreading. For example, if the user types E REDO in the editor, he wants the last event on LISPXHISTORY processed as LISPX input, and not to be unread and processed by the editor.

Note: The editor determines which history commands to pass to LISPX by looking at HISTORYCOMS, a list of the history commands. EDITDEFAULT (page 16.66) interrogates HISTORYCOMS before attempting spelling correction. (All of the commands on HISTORYCOMS are also on EDITCOMSA and EDITCOMSL so that they can be corrected if misspelled in the editor.) Thus if the user defines a LISPXMACRO and wishes it to operate in the editor as well, he need simply add it to

HISTORYCOMS. For example, RETRIEVE is implemented as a LISPXMACRO and works equally well in LISPX and the editor.

The major implementation difference between the editor and LISPX occurs in undoing. EDITHISTORY is a list of only the last N commands, where N is the value of the time-slice. However the editor provides for undoing all changes made in a single editing session, even if that session consisted of more than N edit Therefore, the editor saves undo information commands. independently of the EDITHISTORY on a list called UNDOLST, (although it also stores each entry on UNDOLST in the field of the corresponding event on EDITHISTORY.) Thus, the commands UNDO, !UNDO, and UNBLOCK, are not dependent on EDITHISTORY, and in fact will work if EDITHISTORY = NIL, or even in a system which does not contain LISPX at all. For example, UNDO specifies undoing the last command on UNDOLST, even if that event no longer appears on EDITHISTORY. The only interaction between UNDO and the history list occurs when the user types UNDO followed by an event specification. In this case, the editor calls LISPXFIND to find the event, and then undoes the corresponding entry on UNDOLST. Thus the user can only undo a specified command within the scope of the EDITHISTORY. (Note that this is also the only way UNDO commands themselves can be undone, that is, by using the history feature, to specify the corresponding event, e.g., UNDO UNDO.)

The implementation of the actual undoing is similar to the way it is done in LISPX: each command that makes a change in the structure being edited does so via a function that records the change on a variable. After the command has completed, this variable contains a list of all the pointers that have been changed and their original contents. Undoing that command simply involves mapping down that list and restoring the pointers.

TABLE OF CONTENTS TOC. 1

[This page intentionally left blank]

TOC.2

Occasionally, while a program is running, an error may occur which stops the computation. Errors can be caused in different ways. A coding mistake may have caused the wrong arguments to be passed to a function, or caused the function to try doing something illegal. For example, PLUS will cause an error if its arguments are not numbers. It is also possible to interrupt a computation at any time by typing one of the "interrupt characters," such as control-D or control-E (the Interlisp-D interrupt characters are listed on page 30.1). Finally, the programmer can specify that certain functions automatically cause an error whenever they are entered (see page 15.1). This facilitates debugging by allowing examination of the context within the computation.

When an error occurs, the system can either reset and unwind the stack, or go into a "break", an environment where the user can examine the state of the system at the point of the error, and attempt to debug the program. The mechanism that decides whether to unwind the stack or break can be modified by the user, and is described on page 14.13 of this chapter. Within a break, Interlisp offers an extensive set of "break commands" which assist with debugging.

This chapter explains what happens when errors occur. It also tells the user how to handle program errors using breaks and break commands. The debugging capabilities of break window facility are described, as well as the variables that control its operation. Finally, advanced facilities for modifying and extending the error mechanism are presented.

# 14.1 Breaks

One of the most useful debugging facilities in Interlisp is the ability to put the system into a "break", stopping a computation at any point and allowing the user to interrogate the state of the world and affect the course of the computation. When a break occurs, a "break window" (see page 14.3) is brought up near the tty window of the process that broke. The break window appears to the user like a top-level executive window, except that the prompt character ":" is used to indicate that the executive is ready to accept input, in the same way that " $\leftarrow$ " is

used at the top-level executive. However, a break saves the environment where the break occurred, so that the user may evaluate variables and expressions in the environment that was broken. In addition, the break program recognizes a number of useful "break commands", which provide an easy way to interrogate the state of the broken computation.

Breaks may be entered in several different ways. Some interrupt characters (page 30.1) automatically cause a break to be entered whenever they are typed. Function errors may also cause a break, depending on the depth of the computation (see page 14.13). Finally, Interlisp provides facilities which make it easy to "break" suspect functions so that they always cause a break whenever they are entered, to allow examination and debugging (see page 15.5).

Within a break the user has access to all of the power of Interlisp; he can do anything that he can do at the top-level executive. For example, the user can evaluate an expression, see that the value is incorrect, call the editor, change the function, and evaluate the expression again, all without leaving the break. The user can also type in commands to the programmer's assistant (page 13.1), e.g. to redo or undo previously executed events, including break commands.

Similarly, the user can prettyprint functions, define new functions or redefine old ones, load a file, compile functions, time a computation, etc. In short, anything that he can do at the top level can be done while inside of the break. In addition the user can examine the stack (see page 11.1), and even force a return back to some higher function via the function RETFROM or RETEVAL.

It is important to emphasize that once a break occurs, the user is in complete control of the flow of the computation, and the computation will not proceed without specific instruction from him. If the user types in an expression whose evaluation causes an error, the break is maintained. Similarly if the user aborts a computation initiated from within the break (by typing control-E), the break is maintained. Only if the user gives one of the commands that exits from the break, or evaluates a form which does a RETFROM or RETEVAL back out of BREAK1, will the computation continue. Also, BREAK1 does not "turn off" control-D, so a control-D will force an immediate return back to the top level.

# 14.2 Break Windows

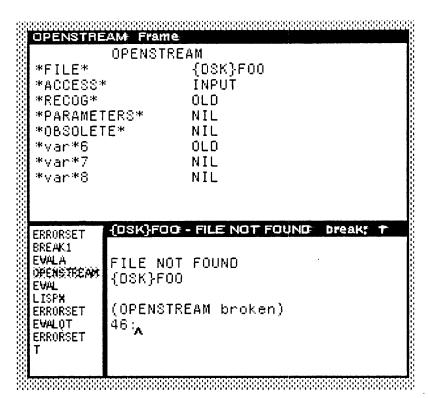

When a break occurs, a break window is brought up near the tty window of the process that broke and the terminal stream switched to it. The title of the break window is changed to give the name of the broken function and the reason for the break. If a break occurs under a previous break, a new break window is created.

Note: If a break is caused by a storage full error, the display break package will not try to open a new break window, since this would cause the error to occur repeatedly.

While in a break window, the clicking middle button brings up a menu of break commands: !EVAL, EVAL, EDIT, revert, ↑, OK, BT, BT!, and ? = . Clicking on most of these commands is equivalent to typing the corresponding break command (page 14.5). Clicking BT and BT!, however, is different from the typed-in backtrace break commands.

The BT and BT! menu commands bring up a backtrace menu beside the break window showing the frames on the stack. BT shows frames for which REALFRAMEP is T; BT! shows all frames. When one of the frames is selected from the backtrace menu, it is graved and the function name and the variables bound in that frame (including local variables and PROG variables) are printed in the "backtrace frame window." If the left button is used for the selection, only named variables are printed. If the middle button is used, all variables are printed (variables without names will appear as \*var\*N). The "backtrace frame" window is an inspect window (see page 26.1). In this window, the left button can be used to select the name of the function, the names of the variables or the values of the variables. For example, below is a picture of a break window with a backtrace menu created by BT. The **OPENSTREAM** stack frame has been selected, so its variables are shown in an inspect window on top of the break window:

ERRORS AND BREAKS

After selecting an item, the middle button brings up a menu of commands that apply to the selected item. If the function name is selected, a choice of editing the function or seeing the compiled code with INSPECTCODE (page 26.2) will be given. If the function is edited in this way, the editor is called in the broken process, so variables evaluated in the editor will be in the broken process.

If a variable name is selected, the command SET will be offered. Selecting SET will READ a value and set the selected to the value read. (Note: The inspector will only allow the setting of named variables. Even with this restriction it is still possible to crash the system by setting variables inside system frames. It is recommended that you exercise caution in setting variables in other than your own code.) If the item selected is a value, the inspector will be called on the selected value.

The internal break variable LASTPOS (page 14.6) is set to the selected frame of the backtrace menu so that the normal break commands EDIT, revert, and ?= work on the currently selected frame. The commands EVAL, revert, ↑, OK, and ?= in the break menu cause the corresponding commands to be "typed in." This means that these break commands will not have the intended effect if characters have already been typed in. Note also that the typed-in break commands BT, BTV, etc. use the value of LASTPOS to determine where to start listing the stack, so selecting a stack frame name in the backtrace menu will effect these commands.

14.4

# 14.3 Break Commands

The basic function of the break package is BREAK1. BREAK1 is just another Interlisp function, not a special system feature like the interpreter or the garbage collector. It has arguments, and returns a value, the same as any other function. For more information on the function BREAK1, see page 14.16.

The value returned by BREAK1 is called "the value of the break." The user can specify this value explicitly by using the RETURN break command (page 14.6). But in most cases, the value of a break is given implicitly, via a GO or OK command, and is the result of evaluating "the break expression." expression, stored in the variable BRKEXP, is an expression equivalent to the computation that would have taken place had no break occurred. For example, if the user breaks on the function FOO, the break expression is the body of the definition of FOO. When the user types OK or GO, the body of FOO is evaluated, and its value returned as the value of the break, i.e., to whatever function called FOO. BRKEXP is set up by the function that created the call to BREAK1. For functions broken with BREAK or TRACE, BRKEXP is equivalent to the body of the definition of the broken function (see page 15.5). For functions broken with BREAKIN, using BEFORE or AFTER, BRKEXP is NIL. For BREAKIN AROUND, BRKEXP is the indicated expression (see page 15.6).

**BREAK1** recognizes a large set of break commands. These are typed in *without* parentheses. In order to facilitate debugging of programs that perform input operations, the carriage return that is typed to complete the **GO**, **OK**, **EVAL**, etc. commands is discarded by **BREAK1**, so that it will not be part of the input stream after the break.

GO

[Break Command]

Evaluates BRKEXP, prints this value, and returns it as the value of the break. Releases the break and allows the computation to proceed.

OK

[Break Command]

Same as GO except that the value of BRKEXP is not printed.

**EVAL** 

[Break Command]

Same as **OK** except that the break is maintained after the evaluation. The value of this evaluation is bound to the local variable **!VALUE**, which the user can interrogate. Typing **GO** or **OK** following **EVAL** will not cause **BRKEXP** to be reevaluated, but simply returns the value of **!VALUE** as the value of the break. Typing another **EVAL** will cause reevaluation. **EVAL** is useful

ERRORS AND BREAKS

	when the user is not sure whether the break will produce the correct value and wishes to examine it before continuing with the computation.
RETURN FORM	[Break Command]
	FORM is evaluated, and returned as the value of the break. For example, one could use the EVAL command and follow this with RETURN (REVERSE!VALUE).
<b>↑</b>	[Break Command]
	Calls ERROR! and aborts the break, making it "go away" without returning a value. This is a useful way to unwind to a higher level break. All other errors, including those encountered while executing the GO, OK, EVAL, and RETURN commands, maintain the break.
	The following four commands refer to "the broken function." This is the function that caused the break, whose name is stored in the BREAK1 argument BRKFN.
!EVAL	[Break Command]
	The broken function is first unbroken, then the break expression is evaluated (and the value stored in !VALUE), and then the function is rebroken. This command is very useful for dealing with recursive functions.
!G0	[Break Command]
	Equivalent to !EVAL followed by GO. The broken function is unbroken, the break expression is evaluated, the function is rebroken, and then the break is exited with the value typed.
!OK	[Break Command]
	Equivalent to !EVAL followed by <b>OK</b> . The broken function is unbroken, the break expression is evaluated, the function is rebroken, and then the break is exited.
UB	[Break Command]
	Unbreaks the broken function.
@	[Break Command]
	Resets the variable LASTPOS, which establishes a context for the commands ?=, ARGS, BT, BTV, BTV*, EDIT, and IN? described below. LASTPOS is the position of a function call on the stack. It is initialized to the function just before the call to BREAK1, i.e., (STKNTH-1'BREAK1).

14.6

Note: When control passes from BREAK1, e.g. as a result of an EVAL, OK, GO, REVERT, ↑ command, or via a RETFROM or RETEVAL typed in by the user, (RELSTK LASTPOS) is executed to release this stack pointer.

- @ treats the rest of the teletype line as its argument(s). It first resets LASTPOS to (STKNTH -1 'BREAK1) and then for each atom on the line, @ searches down the stack for a call to that atom. The following atoms are treated specially:
- @ Do not reset LASTPOS to (STKNTH -1 'BREAK1) but leave it as it was, and continue searching from that point.
- a number N If negative, move LASTPOS down the stack N frames. If positive, move LASTPOS up the stack N frames.
  - / The next atom on the line (which should be a number) specifies that the *previous* atom should be searched for that many times. For example, "@ FOO / 3" is equivalent to "@ FOO FOO".
  - Resets LASTPOS to the value of the next expression, e.g., if the value of FOO is a stack pointer, "@ = FOO FIE" will search for FIE in the environment specified by (the value of) FOO.

For example, if the push-down stack looks like:

- [9] BREAK1
- [8] FOO
- [7] COND
- [6] FIE
- [5] COND
- [4] FIE
- [3] COND
- [2] FIE
- [1] FUM

then "@ FIE COND" will set LASTPOS to the position corresponding to [5]; "@ @ COND" will then set LASTPOS to [3]; and "@ FIE / 3 -1" to [1].

If @ cannot successfully complete a search for function FN, it searches the stack again from that point looking for a call to a function whose name is close to that of FN, in the sense of the spelling corrector (page 20.15). If the search is still unsuccessful, @ types (FN NOT FOUND), and then aborts.

When @ finishes, it types the name of the function at LASTPOS, i.e., (STKNAME LASTPOS).

@ can be used on BRKCOMS (see page 14.17). In this case, the next command on BRKCOMS is treated the same as the rest of the teletype line.

?=

[Break Command]

This is a multi-purpose command. Its most common use is to interrogate the value(s) of the arguments of the broken

function. For example, if FOO has three arguments (X Y Z), then typing? = to a break on FOO will produce:

:?=

X = value of X

Y = value of Y

Z = value of Z

:

? = operates on the rest of the teletype line as its arguments. If the line is empty, as in the above case, it operates on all of the arguments of the broken function. If the user types ? = X (CAR Y), he will see the value of X, and the value of (CAR Y). The difference between using ? = and typing X and (CAR Y) directly to BREAK1 is that ? = evaluates its inputs as of the stack frame LASTPOS, i.e., it uses STKEVAL. This provides a way of examining variables or performing computations as of a particular point on the stack. For example, @ FOO / 2 followed by ? = X will allow the user to examine the value of X in the previous call to FOO, etc.

? = also recognizes numbers as referring to the correspondingly numbered argument, i.e., it uses STKARG in this case. Thus

:@FIE

FIE

:? = 2

will print the name and value of the second argument of FIE.

? = can also be used on BRKCOMS (page 14.17, in which case the next command on BRKCOMS is treated as the rest of the teletype line. For example, if BRKCOMS is (EVAL ? = (X Y) GO), BRKEXP will be evaluated, the values of X and Y printed, and then the function exited with its value being printed.

Note: ?= prints variable values using the function SHOWPRINT (page 25.10), so that if SYSPRETTYFLG = T, the value will be prettyprinted.

?= is a universal mnemonic for displaying argument names and their corresponding values. In addition to being a break command,?= is an edit macro which prints the argument names and values for the current expression (page 16.48), and a read macro (actually? is the read macro character) which does the same for the current level list being read.

PB

[Break Command]

Prints the bindings of a given variable. Similar to ?=, except ascends the stack starting from LASTPOS, and, for each frame in which the given variable is bound, prints the frame name and value of the variable (with PRINTLEVEL reset to (2.3)), e.g.

:PB FOO

@ FN1: 3

@ FN2: 10

@ TOP: NOBIND

PB is also a programmer's assistant command (page 13.17) that can be used when not in a break. PB is implemented via the function PRINTBINDINGS.

[Break Command]

Prints a backtrace of function names only starting at LASTPOS. The value of LASTPOS is changed by selecting an item from the backtrace menu page 14.15 or by the @ command. The several nested calls in system packages such as break, edit, and the top level executive appear as the single entries \*\*BREAK\*\*, \*\*EDITOR\*\*, and \*\*TOP\*\* respectively.

**BTV** 

BT

[Break Command]

Prints a backtrace of function names with variables beginning at LASTPOS.

The value of each variable is printed with the function SHOWPRINT (page 25.10), so that if SYSPRETTYFLG = T, the value will be prettyprinted.

BTV +

[Break Command]

Same as BTV except also prints local variables and arguments to SUBRs.

BTV\*

[Break Command]

Same as BTV except prints arguments to local variables and eval blips (see page 11.14).

BTV!

[Break Command]

Same as BTV except prints everything on the stack.

BT, BTV, BTV+, BTV\*, and BTV! all take optional functional arguments. These arguments are used to choose functions to be skipped on the backtrace. As the backtrace scans down the stack, the name of each stack frame is passed to each of the arguments of the backtrace command. If any of these functions returns a non-NIL value, then that frame is skipped, and not shown in the backtrace. For example, BT EXPRP will skip all functions definied by expr definitions, BTV (LAMBDA (X) (NOT (MEMB X FOOFNS))) will skip all but those functions on FOOFNS. If used on BRKCOMS (page 14.17) the functional argument is no longer optional, i.e., the next element on BRKCOMS must either

be a list of functional arguments, or **NIL** if no functional argument is to be applied.

For BT, BTV, BTV +, BTV\*, and BTV!, if control-P is used to change a printlevel during the backtrace, the printlevel will be restored after the backtrace is completed.

The value of **BREAKDELIMITER**, initially the carriage return character, is printed to delimit the output of ? = and backtrace commands. This can be reset (e.g. to the comma) for more linear output.

#### **ARGS**

# [Break Command]

Prints the names of the variables bound at LASTPOS, i.e., (VARIABLES LASTPOS) (page 11.7). For most cases, these are the arguments to the function entered at that position, i.e., (ARGLIST (STKNAME LASTPOS)).

## **REVERT**

## [Break Command]

Goes back to position LASTPOS on stack and reenters the function called at that point with the arguments found on the stack. If the function is not already broken, REVERT first breaks it, and then unbreaks it after it is reentered.

**REVERT** can be given the position using the conventions described for @, e.g., **REVERT FOO -1** is equivalent to @ **FOO -1** followed by **REVERT**.

**REVERT** is useful for restarting a computation in the situation where a bug is discovered at some point *below* where the problem actually occurred. **REVERT** essentially says "go back there and start over in a break." **REVERT** will work correctly if the names or arguments to the function, or even its function type, have been changed.

#### **ORIGINAL**

# [Break Command]

For use in conjunction with BREAKMACROS (see page 14.17). Form is (ORIGINAL . COMS). COMS are executed without regard for BREAKMACROS. Useful for redefining a break command in terms of itself.

The following two commands are for use only with unbound atoms or undefined function breaks.

#### = FORM

# [Break Command]

Can only be used in a break following an unbound atom error. Sets the atom to the value of *FORM*, exits from the break returning that value, and continues the computation, e.g.,

#### UNBOUND ATOM

# (FOO BROKEN)

: = (COPY FIE)

sets FOO and goes on.

Note: FORM may be given in the form FN[ARGS].

#### -> EXPR

[Break Command]

Can be used in a break following either an unbound atom error, or an undefined function error. Replaces the expression containing the error with *EXPR* (not the value of *EXPR*), and continues the computation. -> does not just change **BRKEXP**; it changes the function or expression containing the erroneous form. In other words, the user does not have to perform any additional editing.

For example,

#### **UNDEFINED CAR OF FORM**

# (FOO1 BROKEN)

:-> FOO

changes the FOO1 to FOO and continues the computation. *EXPR* need not be atomic, e.g.,

#### **UNBOUND ATOM**

#### (FOO BROKEN)

:-> (QUOTE FOO)

For undefined function breaks, the user can specify a function and initial arguments, e.g.,

# UNDEFINED CAR OF FORM MEMBERX

#### (MEMBERX BROKEN)

#### :-> MEMBER X

Note that in the case of a undefined function error occurring immediately following a call to APPLY (e.g., (APPLY X Y) where the value of X is FOO and FOO is undefined), or a unbound atom error immediately following a call to EVAL (e.g., (EVAL X), where the value of X is FOO and FOO is unbound), there is no expression containing the offending atom. In this case, -> cannot operate, so? is printed and no action is taken.

#### **EDIT**

[Break Command]

Designed for use in conjunction with breaks caused by errors. Facilitates editing the expression causing the break:

# **NON-NUMERIC ARG**

NIL

```
. (IPLUS BROKEN)
:EDIT
IN FOO...
(IPLUS X Z)
EDIT
*(3 Y)
*OK
FOO
:
```

and the user can continue by typing OK, EVAL, etc.

This command is very simple conceptually, but its implementation is complicated by all of the exceptional cases involving interactions with compiled functions, breaks on user functions, error breaks, breaks within breaks, et al. Therefore, we shall give the following simplified explanation which will account for 90% of the situations arising in actual usage. For those others, EDIT will print an appropriate failure message and return to the break.

EDIT begins by searching up the stack beginning at LASTPOS (set by @ command, initially position of the break) looking for a form, i.e., an internal call to EVAL. Then EDIT continues from that point looking for a call to an interpreted function, or to EVAL. It then calls the editor on either the EXPR or the argument to EVAL in such a way as to look for an expression EQ to the form that it first found. It then prints the form, and permits interactive editing to begin. Note that the user can then type successive 0's to the editor to see the chain of superforms for this computation.

If the user exits from the edit with an OK, the break expression is reset, if possible, so that the user can continue with the computation by simply typing OK. (Note that evaluating the new BRKEXP will involve reevaluating the form that causes the break, so that if (PUTD (QUOTE (FOO)) BIG-COMPUTATION) were handled by EDIT, BIG-COMPUTATION would be reevaluated.) However, in some situations, the break expression cannot be reset. For example, if a compiled function FOO incorrectly called PUTD and caused the error ARG NOT ATOM followed by a break on PUTD, EDIT might be able to find the form headed by FOO, and also find that form in some higher interpreted function. But after the user corrected the problem in the FOO-form, if any, he would still not have informed EDIT what to do about the immediate problem, i.e., the incorrect call to PUTD. However, if FOO were interpreted, EDIT would find the PUTD form itself, so that when the user corrected that form, EDIT could use the new corrected form to reset the break expression.

[Break Command]

Similar to EDIT, but just prints parent form, and superform, but does not call the editor, e.g.,

ATTEMPT TO RPLAC NIL

Т

(RPLACD BROKEN)

:IN?

FOO: (RPLACD X Z)

Although EDIT and IN? were designed for error breaks, they can also be useful for user breaks. For example, if upon reaching a break on his function FOO, the user determines that there is a problem in the call to FOO, he can edit the calling form and reset the break expression with one operation by using EDIT.

# 14.4 Controlling When to Break

When an error occurs, the system has to decide whether to reset and unwind the stack, or go into a break. In the middle of a complex computation, it is usually helpful to go into a break, so that the user may examine the state of the computation. However, if the computation has only proceeded a little when the error occurs, such as when the user mistypes a function name, the user would normally just terminate a break, and it would be more convenient for the system to simply cause an error and unwind the stack in this situatuation. The decision over whether or not to induce a break depends on the depth of computation, and the amount of time invested in the computation. The actual algorithm is described in detail below; suffice it to say that the parameters affecting this decision have been adjusted empirically so that trivial type-in errors do not cause breaks, but deep errors do.

# (BREAKCHECK ERRORPOS ERXN)

[Function]

**BREAKCHECK** is called by the error routine to decide whether or not to induce a break when a error occurs. *ERRORPOS* is the stack position at which the error occurred; *ERXN* is the error number. Returns T if a break should occur; **NIL** otherwise.

**BREAKCHECK** returns **T** (and a break occurs) if the "computation depth" is greater than or equal to **HELPDEPTH**. **HELPDEPTH** is initially set to 7, arrived at empirically by taking into account the overhead due to **LISPX** or **BREAK**.

If the depth of the computation is less than HELPDEPTH, BREAKCHECK next calculates the length of time spent in the

computation. If this time is greater than HELPTIME milliseconds, initially set to 1000, then BREAKCHECK returns T (and a break occurs), otherwise NIL.

BREAKCHECK determines the "computation depth" by searching back up the stack looking for an ERRORSET frame (ERRORSETs indicate how far back unwinding is to take place when an error occurs, see page 14.21). At the same time, it counts the number of internal calls to EVAL. As soon as the number of calls to EVAL exceeds HELPDEPTH, BREAKCHECK immediately stops searching for an ERRORSET and returns T. Otherwise, BREAKCHECK continues searching until either an ERRORSET is found or the top of the stack is reached. (Note: If the second argument to ERRORSET is INTERNAL, the ERRORSET is ignored by BREAKCHECK during this search.) BREAKCHECK then counts the number of function calls between the error and the last ERRORSET, or the top of the stack. The number of function calls plus the number of calls to EVAL (already counted) is used as the "computation depth".

BREAKCHECK determines the computation time by subtracting the value of the variable HELPCLOCK from the value of (CLOCK 2), the number of milliseconds of compute time (see page 12.15). HELPCLOCK is rebound to the current value of (CLOCK 2) for each computation typed in to LISPX or to a break. The time criterion for breaking can be suppressed by setting HELPTIME to NIL (or a very big number), or by setting HELPCLOCK to NIL. Note that setting HELPCLOCK to NIL will not have any effect beyond the current computation, because HELPCLOCK is rebound for each computation typed in to LISPX and BREAK.

The user can suppress all error breaks by setting the top level binding of the variable HELPFLAG to NIL using SETTOPVAL (HELPFLAG is bound as a local variable in LISPX, and reset to the global value of HELPFLAG on every LISPX line, so just SETQing it will not work.) If HELPFLAG = T (the initial value), the decision whether to cause an error or break is decided based on the computation time and the computation depth, as described above. Finally, if HELPFLAG = BREAK!, a break will always occur following an error.

# 14.5 Break Window Variables

The appearance and use of break windows is controlled by the following variables:

(WBREAK ONFLG)	[Function]
	If ONFLG is non-NIL, break windows and trace windows are
	enabled. If ONFLG is NIL, break windows are disabled (break
	windows do not appear, but the executive prompt is changed to
	":" to indicate that the system is in a break). WBREAK returns T
	if break windows are currently enabled; NIL otherwise.
MaxBkMenuWidth	[Variable]
MaxBkMenuHeight	[Variable]
	The variables MaxBkMenuWidth (default 125) and
	MaxBkMenuHeight (default 300) control the maximum size of
	the backtrace menu. If this menu is too small to contain all of the frames in the backtrace, it is made scrollable in both vertical and horizontal directions.
	D
AUTOBACKTRACEFLG	[Variable]
	This variable controls when and what kind of backtrace menu is automatically brought up. The value of AUTOBACKTRACEFLG can be one of the following:
NIL	The backtrace menu is not automatically brought up (the default).
Т	On error breaks the BT menu is brought up.
BT!	On error breaks the BT! menu is brought up.
ALWAYS	The <b>BT</b> menu is brought up on both error breaks and user breaks (calls to functions broken by <b>BREAK</b> ).
ALWAYS!	On both error breaks and user breaks the BT! menu is brought up.
BACKTRACEFONT	[Variable]
BACKTRACLIONT	The backtrace menu is printed in the font BACKTRACEFONT.
	The backtrace mend is printed in the font BACKTRACE ON 1.
CLOSEBREAKWINDOWFLO	[Variable]
	The system normally closes break windows after the break is
	exited. If CLOSEBREAKWINDOWFLG is NIL, break windows will
	not be closed on exit. Note that in this case, the user must close
	all break windows.
BREAKREGIONSPEC	[Variable]
	Break windows are positioned near the tty window of the
	broken process, as determined by the variable
•	BREAKREGIONSPEC. The value of this variable is a region (page
	27.1) whose LEFT and BOTTOM fields are an offset from the LEFT
	and BOTTOM of the tty window. The WIDTH and HEIGHT fields
	of BREAKREGIONSPEC determine the size of the break window.

TRACEWINDOW	[Variable]	
	The trace window, TRACEWINDOW, is used for tracing functions. It is brought up when the first tracing occurs and stays up until the user closes it. TRACEWINDOW can be set to a particular window to cause the tracing formation to print there.	
TRACEREGION	[Variable]	
	The trace window is first created in the region TRACEREGION.	

# 14.6 Creating Breaks with BREAK1

The basic function of the break package is BREAK1, which creates a break. A break appears to be a regular executive, with the prompt ":", but BREAK1 also detects and interpretes break commands (page 14.5).

# (BREAK1 BRKEXP BRKWHEN BRKFN BRKCOMS BRKTYPE ERRORN)

[NLambda Function]

If BRKWHEN (evaluated) is non-NIL, a break occurs and commands are then taken from BRKCOMS or the terminal and interpreted. All inputs not recognized by BREAK1 are simply passed on to the programmer's assistant.

If BRKWHEN is NIL, BRKEXP is evaluated and returned as the value of BREAK1, without causing a break.

When a break occurs, if *ERRORN* is a list whose CAR is a number, *ERRORMESS* (page 14.20) is called to print an identifying message. If *ERRORN* is a list whose CAR is not a number, *ERRORMESS1* (page 14.21) is called. Otherwise, no preliminary message is printed. Following this, the message (*BRKFN* broken) is printed.

Since BREAK1 itself calls functions, when one of these is broken, an infinite loop would occur. BREAK1 detects this situation, and prints Break within a break on FN, and then simply calls the function without going into a break.

The commands GO, !GO, OK, !OK, RETURN and ↑ are the only ways to leave BREAK1. The command EVAL causes BRKEXP to be evaluated, and saves the value on the variable !VALUE. Other commands can be defined for BREAK1 via BREAKMACROS (below).

BRKTYPE is NIL for user breaks, INTERRUPT for control-H breaks, and ERRORX for error breaks. For breaks when BRKTYPE is not NIL, BREAK1 will clear and save the input buffer. If the break

returns a value (i.e., is not aborted via  $\uparrow$  or control-D) the input buffer will be restored.

The fourth argument to BREAK1 is BRKCOMS, a list of break commands that BREAK1 interprets and executes as though they were keyboard input. One can think of BRKCOMS as another input file which always has priority over the keyboard. Whenever BRKCOMS = NIL, BREAK1 reads its next command from the keyboard. Whenever BRKCOMS is not NIL, BREAK1 takes (CAR BRKCOMS) as its next command and sets BRKCOMS to (CDR BRKCOMS). For example, suppose the user wished to see the value of the variable X after a function was evaluated. He could set up a break with BRKCOMS = (EVAL (PRINT X) OK), which would have the desired effect. Note that if BRKCOMS is not NIL, the value of a break command is not printed. If you desire to see a value, you must print it yourself, as in the above example. The function TRACE (page 15.5) uses BRKCOMS: it sets up a break with two commands; the first one prints the arguments of the function, or whatever the user specifies, and the second is the command GO, which causes the function to be evaluated and its value printed.

Note: If an error occurs while interpreting the *BRKCOMS* commands, *BRKCOMS* is set to **NIL**, and a full interactive break occurs.

The break package has a facility for redirecting ouput to a file. All output resulting from *BRKCOMS* will be output to the value of the variable *BRKFILE*, which should be the name of an open file. Output due to user typein is not affected, and will always go to the terminal. *BRKFILE* is initially T.

#### **BREAKMACROS**

[Variable]

**BREAKMACROS** is a list of the form ( $(NAME_1 COM_{11} ... COM_{1n})$ ) ( $NAME_2 COM_{21} ... COM_{2n}$ ) ...). Whenever an atomic command is given to **BREAK1**, it first searches the list **BREAKMACROS** for the command. If the command is equal to  $NAME_i$ , **BREAK1** simply appends the corresponding commands to the front of *BRKCOMS*, and goes on. If the command is not found on **BREAKMACROS**, **BREAK1** then checks to see if it is one of the built in commands, and finally, treats it as a function or variable as before.

If the command is not the name of a defined function, bound variable, or LISPX command, BREAK1 will attempt spelling correction using BREAKCOMSLST as a spelling list. If spelling correction is unsuccessful, BREAK1 will go ahead and call LISPX anyway, since the atom may also be a misspelled history command.

For example, the command ARGS could be defined by including on BREAKMACROS the form:

(ARGS (PRINT (VARIABLES LASTPOS T)))

#### (BREAKREAD TYPE)

[Function]

Useful within BREAKMACROS for reading arguments. If BRKCOMS is non-NIL (the command in which the call to BREAKREAD appears was not typed in), returns the next break command from BRKCOMS, and sets BRKCOMS to (CDR BRKCOMS).

If BRKCOMS is NIL (the command was typed in), then BREAKREAD returns either the rest of the commands on the line as a list (if TYPE = LINE) or just the next command on the line (if TYPE is not LINE).

For example, the BT command is defined as (BAKTRACE LASTPOS NIL (BREAKREAD 'LINE) 0 T). Thus, if the user types BT, the third argument to BAKTRACE will be NIL. If the user types BT SUBRP, the third argument will be (SUBRP).

#### **BREAKRESETFORMS**

[Variable]

If the user is developing programs that change the way a user and Interlisp normally interact (e.g., change or disable the interrupt or line-editing characters, turn off echoing, etc.), debugging them by breaking or tracing may be difficult, because Interlisp might be in a "funny" state at the time of the break. BREAKRESETFORMS is designed to solve this problem. The user puts on BREAKRESETFORMS expressions suitable for use in conjunction with RESETFORM or RESETSAVE (page 14.24). When a break occurs, BREAK1 evaluates each expression on BREAKRESETFORMS before any interaction with the terminal, and saves the values. When the break expression is evaluated via an EVAL, OK, or GO, BREAK1 first restores the state of the system with respect to the various expressions on BREAKRESETFORMS. When control returns to BREAK1, the expressions on BREAKRESETFORMS are again evaluated, and their values saved. When the break is exited with an OK, GO, RETURN, or † command, by typing control-D, or by a RETFROM or RETEVAL typed in by the user, BREAK1 again restores state. Thus the net effect is to make the break invisible with respect to the user's programs, but nevertheless allow the user to interact in the break in the normal fashion.

Note: All user type-in is scanned in order to make the operations undoable as described on page 13.27. At this point, RETFROMs and RETEVALs are also noticed. However, if the user types in an expression which calls a function that then does a RETFROM, this RETFROM will not be noticed, and the effects of BREAKRESETFORMS will not be reversed.

As mentioned earlier, BREAK1 detects "Break within a break" situations, and avoids infinite loops. If the loop occurs because of an error, BREAK1 simply rebinds BREAKRESETFORMS to NIL, and calls HELP. This situation most frequently occurs when there is a bug in a function called by BREAKRESETFORMS.

Note: SETQ expressions can also be included on BREAKRESETFORMS for saving and restoring system parameters, e.g. (SETQ LISPXHISTORY NIL), (SETQ DWIMFLG NIL), etc. These are handled specially by BREAK1 in that the current value of the variable is saved before the SETQ is executed, and upon restoration, the variable is set back to this value.

# 14.7 Signalling Errors

#### (ERRORX ERXM)

[Function]

The entry to the error routines. If ERXM = NIL, (ERRORN) is used to determine the error-message. Otherwise, (SETERRORN (CAR ERXM) (CADR ERXM)) is performed, "setting" the error number and argument. Thus following either (ERRORX '(10 T)) or (PLUS T), (ERRORN) is (10 T). ERRORX calls BREAKCHECK, and either induces a break or prints the message and unwinds to the last ERRORSET (page 14.13). Note that ERRORX can be called by any program to intentionally induce an error of any type. However, for most applications, the function ERROR will be more useful.

#### (ERROR MESS1 MESS2 NOBREAK)

[Function]

Prints MESS1 (using PRIN1), followed by a space if MESS1 is an atom, otherwise a carriage return. Then MESS2 is printed (using PRIN1 if MESS2 is a string, otherwise PRINT). For example, (ERROR "NON-NUMERIC ARG" T) prints

#### **NON-NUMERIC ARG**

Т

and (ERROR 'FOO "NOT A FUNCTION") prints FOO NOT A FUNCTION. If both *MESS1* and *MESS2* are NIL, the message printed is simply ERROR.

If NOBREAK = T, ERROR prints its message and then coss ERROR! (below). Otherwise it calls (ERRORX '(17 (MESS1 . ME > S2))), i.e., generates error number 17, in which case the decision as to whether or not to break, and whether or not to print a message, is handled as per any other error.

If the value of **HELPFLAG** (page 14.14) is **BREAK!**, a break will always occur, irregardless of the value of *NOBREAK*.

Note: If ERROR causes a break, the "break expression" (page 14.5) will be (ERROR MESS1 MESS2 NOBREAK). Using the GO, OK, or EVAL break commands (page 14.5) will simply call ERROR again. It is sometimes helpful to design programs that call ERROR such that if the call to ERROR returns (as the result of using the RETURN break command), the operation is tried again. This allows the use to fix any problems within the break environment, and try to continue the operation.

(HELP MESS1 MESS2 BRKT	YPE) [Function]	
	Prints MESS1 and MESS2 similar to ERROR, and then calls BREAK1	
	passing BRKTYPE as the BRKTYPE argument. If both MESS1 and	
	MESS2 are NIL, Help! is used for the message. HELP is a	
	convenient way to program a default condition, or to terminate	
	some portion of a program which the computation is	
	theoretically never supposed to reach.	
(SHOULDNT MESS)	[Function]	
	Useful in those situations when a program detects a condition	
	that should never occur. Calls HELP with the message arguments	
	MESS and "Shouldn't happen!" and a BRKTYPE argument of 'ERRORX.	
(ERROR!)	[Function]	
	Programmable control-E; immediately returns from last	
	ERRORSET or resets.	
(DECET)	fe	
(RESET)	[Function]	
	Programmable control-D; immediately returns to the top level.	
(ERRORN)	[Function]	
	Returns information about the last error in the form (NUM EXP)	
	where NUM is the error number (page 14.27) and EXP is the	
	expression which was printed out after the error message. For	
	example, following (PLUS T), (ERRORN) would return (10 T).	
(SETERRORN NUM MESS)	[Function	
Accession to the supplementary of the supplementary	Sets the value returned by ERRORN to (NUM MESS).	
(FDD 0 D14566 + 1)	re	
(FRRORMESS U)	[Function	
	Prints message corresponding to an ERRORN that yielded $U$ . For example, (ERRORMESS '(10 T)) would print	
	NON-NUMERIC ARG	
	Т	

14.20 ERRORS AND BREAKS

#### (ERRORMESS1 MESS1 MESS2 MESS3)

[Function]

Prints the message corresponding to a HELP or ERROR break.

#### (ERRORSTRING X)

[Function

Returns as a new string the message corresponding to error number X, e.g., (ERRORSTRING 10) = "NON-NUMERIC ARG".

# 14.8 Catching Errors

All error conditions are not caused by program bugs. For some programs, it is reasonable for some errors to occur (such as file not found errors) and it is possible for the program to handle the error itself. There are a number of functions that allow a program to "catch" errors, rather than abort the computation or cause a break.

#### (ERRORSET FORM FLAG —)

[Function]

Performs (EVAL FORM). If no error occurs in the evaluation of FORM, the value of ERRORSET is a list containing one element, the value of (EVAL FORM). If an error did occur, the value of ERRORSET is NIL.

**ERRORSET** is a lambda function, so its arguments are evaluated before it is entered, i.e., (ERRORSET X) means EVAL is called with the value of X. In most cases, ERSETQ and NLSETQ (below) are more useful.

Performance Note: When a call to ERSETQ or NLSETQ is compiled, the form to be evaluated is compiled as a separate function. However, compiling a call to ERRORSET does not compile FORM. Therefore, if FORM performs a lengthy computation, using ERSETQ or NLSETQ can be much more efficient than using ERRORSET.

The argument FLAG controls the printing of error messages if an error occurs. Note that if a break occurs below an ERRORSET, the message is printed regardless of the value of FLAG.

If FLAG = T, the error message is printed; if FLAG = NIL, the error message is not printed (unless NLSETQGAG is NIL, see below).

If FLAG = INTERNAL, this ERRORSET is ignored for the purpose of deciding whether or not to break or print a message (see page 14.13). However, the ERRORSET is in effect for the purpose of flow of control, i.e., if an error occurs, this ERRORSET returns NIL.

If FLAG = NOBREAK, no break will occur, even if the time criterion for breaking is met (see page 14.13). Note that FLAG = NOBREAK will not prevent a break from occurring if the

	error occurs more than HELPDEPTH function calls below the errorset, since BREAKCHECK will stop searching before it reaches the ERRORSET. To guarantee that no break occurs, the user would also either have to reset HELPDEPTH or HELPFLAG (page 14.13).
(ERSETQ FORM)	[NLambda Function]
	Performs (ERRORSET 'FORM T), evaluating FORM and printing error messages.
(NLSETQ FORM)	[NLambda Function]
	Performs (ERRORSET 'FORM NIL), evaluating FORM without printing error messages.
NLSETQGAG	[Variable]
	If <b>NLSETQGAG</b> is <b>NIL</b> , error messages will print, regardless of the <i>FLAG</i> argument of <b>ERRORSET</b> . <b>NLSETQGAG</b> effectively changes all <b>NLSETQs</b> to <b>ERSETQs</b> . <b>NLSETQGAG</b> is initially <b>T</b> .
	Occasionally the user may want to treat certain types of errors differently from others, e.g., always break, never break, or perhaps take some corrective action. This can be accomplished via ERRORTYPELST:
ERRORTYPELST	[Variable]
	ERRORTYPELST is a list of elements, where each element is of the form (NUM FORM <sub>1</sub> FORM <sub>N</sub> ). NUM is one of the error numbers (page 14.27). During an error, after BREAKCHECK has been completed, but before any other action is taken, ERRORTYPELST is searched for an element with the same error number as that causing the error. If one is found, the corresponding forms are evaluated, and if the last one produces a non-NIL value, this value is substituted for the offender, and the function causing the error is reentered.  Note: ERRORTYPELST is accessed as a special variable (see page 18.5), so it can be rebound in a function argument list of PROG form to catch errors in a dynamic context.
	Within ERRORTYPELST entries, the following variables may be useful:
ERRORMESS	[Variable]
	CAR is the error number, CADR the "offender", e.g., (10 NIL) corresponds to a NON-NUMERIC ARG NIL error.

#### **ERRORPOS**

[Variable]

Stack pointer to the function in which the error occurred, e.g., (STKNAME ERRORPOS) might be IPLUS, RPLACA, INFILE, etc.

Note: If the error is going to be handled by a RETFROM, RETTO, or a RETEVAL in the ERRORTYPELST entry, it probably is a good idea to first release the stack pointer ERRORPOS, e.g. by performing (RELSTK ERRORPOS).

#### **BREAKCHK**

[Variable]

Value of **BREAKCHECK**, i.e., T means a break will occur, **NIL** means one will not. This may be reset within the **ERRORTYPELST** entry.

#### **PRINTMSG**

[Variable]

If T, means print error message, if NIL, don't print error message, i.e., corresponds to second argument to ERRORSET. The user can force or suppress the printing of error messages for various error types by including on ERRORTYPELST an expression which explicitly sets PRINTMSG.

For example, putting

[10 (AND (NULL (CADR ERRORMESS))
(SELECTQ (STKNAME ERRORPOS)
((IPLUS ADD1 SUB1) 0)
(ITIMES 1)
(PROGN (SETQ BREAKCHK T) NIL]

on ERRORTYPELST would specify that whenever a NON-NUMERIC ARG - NIL error occurred, and the function in question was IPLUS, ADD1, or SUB1, 0 should be used for the NIL. If the function was ITIMES, 1 should be used. Otherwise, always break. Note that the latter case is achieved not by the value returned, but by the effect of the evaluation, i.e., setting BREAKCHK to T. Similarly, (16 (SETQ BREAKCHK NIL)) would prevent END OF FILE errors from ever breaking.

ERRORTYPELST is initially ((23 (SPELLFILE (CADR ERRORMESS) NIL NOFILESPELLFLG))), which causes SPELLFILE to be called in case of a FILE NOT FOUND error (see page 24.32). If SPELLFILE is successful, the operation will be reexecuted with the new (corrected) file name.

# 14.9 Changing and Restoring System State

In Interlisp, a computation can be interrupted/aborted at any point due to an error, or more forcefully, because a control-D was typed, causing return to the top level. This situation creates problems for programs that need to perform a computation with the system in a "different state", e.g., different radix, input file, readtable, etc. but want to be able to restore the state when the computation has completed. While program errors and control-E can be "caught" by ERRORSETs, control-D is not. Note that the program could redefine control-D as a user interrupt (page 30.3), check for it, reenable it, and call RESET or something similar. Thus the system may be left in its changed state as a result of the computation being aborted. The following functions address this problem.

Note that these functions cannot handle the situation where their environment is exited via anything other than a normal return, an error, or a reset. Therefore, a RETEVAL, RETFROM, RESUME, etc., will never be seen.

#### (RESETLST $FORM_1 \dots FORM_N$ )

[NLambda NoSpread Function]

**RESETLST** evaluates its arguments in order, after setting up an **ERRORSET** so that any reset operations performed by **RESETSAVE** (see below) are restored when the forms have been evaluated (or an error occurs, or a control-D is typed). If no error occurs, the value of **RESETLST** is the value of *FORM*<sub>N</sub>, otherwise **RESETLST** generates an error (after performing the necessary restorations).

RESETLST compiles open.

#### (RESETSAVE X Y)

[NLambda NoSpread Function]

**RESETSAVE** is used within a call to **RESETLST** to change the system state by calling a function or setting a variable, while specifying how to restore the original system state when the **RESETLST** is exited (normally, or with an error or control-D).

If X is atomic, resets the top level value of X to the value of Y. For example, (RESETSAVE LISPXHISTORY EDITHISTORY) resets the value of LISPXHISTORY to the value of EDITHISTORY, and provides for the original value of LISPXHISTORY to be restored when the RESETLST completes operation, (or an error occurs, or a control-D is typed).

Note: If the variable is simply rebound, the RESETSAVE will not affect the most recent binding but will change only the top level value, and therefore probably not have the intended effect.

If X is not atomic, it is a form that is evaluated. If Y is NIL, X must return as its value its "former state", so that the effect of evaluating the form can be reversed, and the system state can be restored, by applying CAR of X to the value of X. For example,

(RESETSAVE (RADIX 8)) performs (RADIX 8), and provides for RADIX to be reset to its original value when the RESETLST completes by applying RADIX to the value returned by (RADIX 8).

In the special case that CAR of X is SETQ, the SETQ is transparent for the purposes of RESETSAVE, i.e. the user could also have written (RESETSAVE (SETQ X (RADIX 8))), and restoration would be performed by applying RADIX, not SETQ, to the previous value of RADIX.

If Y is not NIL, it is evaluated (before X), and its value is used as the restoring expression. This is useful for functions which do not return their "previous setting". For example,

#### [RESETSAVE (SETBRK ...) (LIST 'SETBRK (GETBRK]

will restore the break characters by applying SETBRK to the value returned by (GETBRK), which was computed before the (SETBRK ...) expression was evaluated. Note that the restoration expression is "evaluated" by applying its CAR to its CDR. This insures that the "arguments" in the CDR are not evaluated again.

If X is NIL, Y is still treated as a restoration expression. Therefore, (RESETSAVE NIL (LIST'CLOSEF FILE))

will cause FILE to be closed when the RESETLST that the RESETSAVE is under completes (or an error occurs or a control-D is typed).

Note: RESETSAVE can be called when *not* under a RESETLST. In this case, the restoration will be performed at the next RESET, i.e., control-D or call to RESET. In other words, there is an "implicit" RESETLST at the top-level executive.

**RESETSAVE** compiles open. Its value is not a "useful" quantity.

#### (RESETVAR VAR NEWVALUE FORM)

[NLambda Function]

Simplified form of RESETLST and RESETSAVE for resetting and restoring global variables. Equivalent to (RESETLST (RESETSAVE VAR NEWVALUE) FORM). For example, (RESETVAR LISPXHISTORY EDITHISTORY (FOO)) resets LISPXHISTORY to the value of EDITHISTORY while evaluating (FOO). RESETVAR compiles open. If no error occurs, its value is the value of FORM.

#### (RESETVARS VARSLST E1 E2 ... EN)

[NLambda NoSpread Function]

Similar to **PROG**, except that the variables in *VARSLST* are global variables. In a deep bound system (such as Interlisp-D), each variable is "rebound" using **RESETSAVE**.

In a shallow bound system (such as Interlisp-10) RESETVARS and PROG are identical, except that the compiler insures that

variables bound in a RESETVARS are declared as SPECVARS (see page 18.5).

RESETVARS, like GETATOMVAL and SETATOMVAL (page 2.4), is provided to permit compatibility (i.e. transportability) between a shallow bound and deep bound system with respect to conceptually global variables.

Note: Like PROG, RESETVARS returns NIL unless a RETURN statement is executed.

#### (RESETFORM RESETFORM FORM<sub>1</sub> FORM<sub>2</sub> ... FORM<sub>N</sub>)

[NLambda NoSpread Function]

Simplified form of RESETLST and RESETSAVE for resetting a system state when the corresponding function returns as its value the "previous setting." Equivalent to (RESETLST (RESETSAVE RESETFORM) FORM<sub>1</sub> FORM<sub>2</sub> ... FORM<sub>N</sub>). For example, (RESETFORM (RADIX 8) (FOO)). RESETFORM compiles open. If no error occurs, it returns the value returned by FORM<sub>N</sub>.

For some applications, the restoration operation must be different depending on whether the computation completed successfully or was aborted somehow (e.g., by an error or by typing control-D). To facilitate this, while the restoration operation is being performed, the value of RESETSTATE will be bound to NIL, ERROR, RESET, or HARDRESET depending on whether the exit was normal, due to an error, due to a reset (i.e., control-D), or due to call to HARDRESET (page 23.1). As an example of the use of RESETSTATE,

```
(RESETLST

(RESETSAVE (INFILE X)

(LIST '[LAMBDA (FL)

(COND ( (EQ RESETSTATE 'RESET)

(CLOSEF FL)

(DELFILE FL]

X))

FORMS)
```

will cause **X** to be closed and deleted only if a control-D was typed during the execution of *FORMS*.

When specifying complicated restoring expressions, it is often necessary to use the old value of the saving expression. For example, the following expression will set the primary input file (to FL) and execute some forms, but reset the primary input file only if an error or control-D occurs.

```
(RESETLST
(SETQ TEM (INPUT FL))
(RESETSAVE NIL
(LIST '(LAMBDA (X) (AND RESETSTATE (INPUT X)))
TEM))
```

#### FORMS)

So that you will not have to explicitly save the old value, the variable **OLDVALUE** is bound at the time the restoring operation is performed to the value of the saving expression. Using this, the previous example could be recoded as:

(RESETLST
(RESETSAVE (INPUT FL)
'(AND RESETSTATE (INPUT OLDVALUE)))
FORMS)

As mentioned earlier, restoring is performed by applying CAR of the restoring expression to the CDR, so RESETSTATE and (INPUT OLDVALUE) will not be evaluated by the APPLY. This particular example works because AND is an nlambda function that explicitly evaluates its arguments, so APPLYing AND to (RESETSTATE (INPUT OLDVALUE)) is the same as EVALing (AND RESETSTATE (INPUT OLDVALUE)). PROGN also has this property, so you can use a lambda function as a restoring form by enclosing it within a PROGN.

The function **RESETUNDO** (page 13.30) can be used in conjunction with **RESETLST** and **RESETSAVE** to provide a way of specifying that the system be restored to its prior state by *undoing* the side effects of the computations performed under the **RESETLST**.

#### 14.10 Error List

There are currently fifty-plus types of errors in the Interlisp system. Some of these errors are implementation dependent, i.e., appear in Interlisp-D but may not appear in other Interlisp systems. The error number is set internally by the code that detects the error before it calls the error handling functions. It is also the value returned by ERRORN if called subsequent to that type of error, and is used by ERRORMESS for printing the error message.

Most errors will print the offending expression following the message, e.g., NON-NUMERIC ARG NIL is very common. Error number 18 (control-B) always causes a break (unless HELPFLAG is NIL). All other errors cause breaks if BREAKCHECK returns T (see page 14.13).

The errors are listed below by error number:

#### 0 SYSTEM ERROR

Low-level Interlisp system error. It is quite possible that random programs or data structures might have already been smashed.

Unless he is sure he knows what the problem is, the user is best advised to save any important information, and reload the Interlisp system as soon as possible.

1 No longer used.

#### 2 STACK OVERFLOW

Occurs when computation is too deep, either with respect to number of function calls, or number of variable bindings. Usually because of a non-terminating recursive computation, i.e., a bug.

#### 3 ILLEGAL RETURN

Call to **RETURN** when not inside of an interpreted **PROG**.

#### 4 ARG NOT LIST

RPLACA called on a non-list.

#### 5 HARD DISK ERROR

An error with the local disk drive.

#### 6 ATTEMPT TO SET NIL

Via SET or SETQ

#### 7 ATTEMPT TO RPLAC NIL

Attempt either to RPLACA or to RPLACD NIL with something other than NIL.

#### 8 UNDEFINED OR ILLEGAL GO

GO when not inside of a PROG, or GO to nonexistent label.

#### 9 FILE WON'T OPEN

From OPENSTREAM (page 24.2).

#### 10 NON-NUMERIC ARG

A numeric function e.g., PLUS, TIMES, GREATERP, expected a number.

#### 11 ATOM TOO LONG

Attempted to create a litatom (via PACK, or typing one in, or reading from a file) with too many characters. In Interlisp-D, the maximum number of characters in a litatom is 255.

#### 12 ATOM HASH TABLE FULL

No room for any more (new) atoms.

#### 13 FILE NOT OPEN

From an I/O function, e.g., READ, PRINT, CLOSEF.

#### 14 ARG NOT LITATOM

SETQ, PUTPROP, GETTOPVAL, etc., given a non-atomic arg.

#### 15 TOO MANY FILES OPEN

#### 16 END OF FILE

From an input function, e.g., READ, READC, RATOM. After the error occurs, the file will still be left open.

Note: It is possible to use an ERRORTYPELST entry (page 14.22) to return a character as the value of the call to ERRORX, and the program will continue, e.g. returning "]" may be used to complete a read operation.

#### 17 ERROR

Call to ERROR (page 14.19).

#### 18 BREAK

Control-B was typed.

#### 19 ILLEGAL STACK ARG

A stack function expected a stack position and was given something else. This might occur if the arguments to a stack function are reversed. Also occurs if user specified a stack position with a function name, and that function was not found on the stack. See page 11.1.

#### 20 FAULT IN EVAL

Artifact of bootstrap process. Never occurs after FAULTEVAL is defined.

#### 21 ARRAYS FULL

System will first initiate a garbage collection of array space, and if no array space is reclaimed, will then generate this error.

#### 22 FILE SYSTEM RESOURCES EXCEEDED

Includes no more disk space, disk quota exceeded, directory full, etc.

#### 23 FILE NOT FOUND

File name does not correspond to a file in the corresponding directory. Can also occur if file name is ambiguous.

Interlisp is initialized with an entry on ERRORTYPELST (page 14.22) to call SPELLFILE for this error. SPELLFILE will search alternate directories or perform spelling correction on the connected directory. If SPELLFILE fails, then the user will see this error.

## 24 BAD SYSOUT FILE

Date does not agree with date of MAKESYS, or file is not a sysout file at all (see page 12.8).

#### 25 UNUSUAL CDR ARG LIST

A form ends in a non-list other than NIL, e.g., (CONS T. 3).

#### 26 HASH TABLE FULL

See hash array functions, page 6.1.

#### 27 ILLEGAL ARG

Catch-all error. Currently used by PUTD, EVALA, ARG, FUNARG, etc.

#### 28 ARG NOT ARRAY

**ELT** or **SETA** given an argument that is not a legal array (see page 5.1).

#### 29 ILLEGAL OR IMPOSSIBLE BLOCK

(Interlisp-10) Not enough free blocks available (from GETBLK or RELBLK).

#### 30 STACK PTR HAS BEEN RELEASED

A released stack pointer was supplied as a stack descriptor for a purpose other than as a stack pointer to be re-used (see page 11.10).

#### 31 STORAGE FULL

Following a garbage collection, if not enough words have been collected, and there is no un-allocated space left in the system, this error is generated.

#### 32 ATTEMPT TO USE ITEM OF INCORRECT TYPE

Before a field of a user data type is changed, the type of the item is first checked to be sure that it is the expected type. If not, this error is generated (see page 8.20).

#### 33 ILLEGAL DATA TYPE NUMBER

The argument is not a valid user data type number (see page 8.20).

#### 34 DATA TYPES FULL

All available user data types have been allocated (see page 8.20).

#### 35 ATTEMPT TO BIND NIL OR T

In a PROG or LAMBDA expression.

#### **36 TOO MANY USER INTERRUPT CHARACTERS**

Attempt to enable a user interrupt character when all user channels are currently enabled (see page 30.3).

#### 37 READ-MACRO CONTEXT ERROR

(Interlisp-10 only) Occurs when a READ is executed from within a read macro function and the next token is a ) or a ] (see page 25.39).

#### 38 ILLEGAL READTABLE

The argument was expected to be a valid read table (see page 25.33).

#### 39 ILLEGAL TERMINAL TABLE

The argument was expected to be a valid terminal table (see page 30.4).

#### 40 SWAPBLOCK TOO BIG FOR BUFFER

(Interlisp-10) An attempt was made to swap in a function/array which is too large for the swapping buffer.

#### 41 PROTECTION VIOLATION

Attempt to open a file that user does not have access to. Also reference to unassigned device.

#### 42 BAD FILE NAME

Illegal character in file specification, illegal syntax, e.g. two;'s etc.

#### 43 USER BREAK

Error corresponding to user interrupt character. See page 30.3.

#### 44 UNBOUND ATOM

This occurs when a variable (litatom) was used which had neither a stack binding (wasn't an argument to a function nor a PROG variable) nor a top level value. The "culprit" ((CADR ERRORMESS)) is the litatom. Note that if DWIM corrects the error, no error occurs and the error number is not set. However, if an error is going to occur, whether or not it will cause a break, the error number will be set.

#### 45 UNDEFINED CAR OF FORM

Undefined function error. This occurs when a form is evaluated whose function position (CAR) does not have a definition as a function. Culprit is the form.

#### **46 UNDEFINED FUNCTION**

This error is generated if APPLY is given an undefined function. Culprit is (LIST FN ARGS)

#### 47 CONTROL-E

The user typed control-E.

#### 48 FLOATING UNDERFLOW

Underflow during floating-point operation.

#### 49 FLOATING OVERFLOW

Overflow during floating-point operation.

## 50 **OVERFLOW**

Overflow during integer operation.

#### 51 ARG NOT HARRAY

Hash array operations given an argument that is not a hash array.

#### 52 TOO MANY ARGUMENTS

Too many arguments given to a lambda-spread, lambda-nospread, or nlambda-spread function.

Note that Interlisp-D does not cause an error if more arguments are passed to a function than it is defined with. This argument occurs when more individual arguments are passed to a function than Interlisp-D can store on the stack at once. The limit is currently 80 arguments.

In addition, many system functions, e.g., DEFINE, ARGLIST, ADVISE, LOG, EXPT, etc, also generate errors with appropriate messages by calling ERROR (see page 14.19) which causes error number 17.

# 15. BREAKING, TRACING, AND ADVISING

It is frequently useful to be able to modify the behavior of a function without actually editing its definition. Interlisp provides several different facilities for doing this. By "breaking" a function, the user can cause breaks to occur at various times in the running of an incomplete program, so that the program state can be inspected. "Tracing" a function causes information to be printed every time the function is entered or exited. These are very useful debugging tools.

"Advising" is a facility for specifying longer-term function modifications. Even system functions can be changed through advising.

# 15.1 Breaking Functions and Debugging

Debugging a collection of LISP functions involves isolating problems within particular functions and/or determining when and where incorrect data are being generated and transmitted. In the Interlisp system, there are three facilities which allow the user to (temporarily) modify selected function definitions so that he can follow the flow of control in his programs, and obtain this debugging information. All three redefine functions in terms of a system function, BREAK1 (see page 14.16).

**BREAK** (page 15.5) modifies the definition of a function *FN*, so that whenever *FN* is called and a break condition (defined by the user) is satisfied, a function break occurs. The user can then interrogate the state of the machine, perform any computation, and continue or return from the call.

**TRACE** (page 15.5) modifies a definition of a function *FN* so that whenever *FN* is called, its arguments (or some other values specified by the user) are printed. When the value of *FN* is computed it is printed also. **TRACE** 15 a special case of **BREAK**.

**BREAKIN** (page 15.6) allows the user to insert a breakpoint *inside* an expression defining a function. When the breakpoint is reached and if a break condition (defined by the user) is satisfied, a temporary halt occurs and the user can again investigate the state of the computation.

The following two examples illustrate these facilities. In the first example, the user traces the function FACTORIAL. TRACE redefines FACTORIAL so that it print its arguments and value, and then goes on with the computation. When an error occurs on the fifth recursion, a full interactive break occurs. The situation is then the same as though the user had originally performed (BREAK FACTORIAL) instead of (TRACE FACTORIAL), and the user can evaluate various Interlisp forms and direct the course of the computation. In this case, the user examines the variable N, and instructs BREAK1 to return 1 as the value of this cell to FACTORIAL. The rest of the tracing proceeds without incident. The user would then presumably edit FACTORIAL to change L to 1.

# change L to 1. ←PP FACTORIAL (FACTORIAL [LAMBDA (N) (COND ((ZEROP N) L) (T (ITIMES N (FACTORIAL (SUB1 N]) **FACTORIAL** ←(TRACE FACTORIAL) (FACTORIAL) ←(FACTORIAL 4) FACTORIAL: N = 4**FACTORIAL:** N = 3**FACTORIAL:** N = 2**FACTORIAL:** N = 1FACTORIAL: N = 0**UNBOUND ATOM** L (FACTORIAL BROKEN) :N 0 :RETURN 1

FACTORIAL = 1

```
FACTORIAL = 1
FACTORIAL = 2
FACTORIAL = 6
FACTORIAL = 24
24
```

In the second example, the user has constructed a non-recursive definition of FACTORIAL. He uses BREAKIN to insert a call to BREAK1 just after the PROG label LOOP. This break is to occur only on the last two iterations, when N is less than 2. When the break occurs, the user tries to look at the value of N, but mistakenly types NN. The break is maintained, however, and no damage is done. After examining N and M the user allows the computation to continue by typing OK. A second break occurs after the next iteration, this time with N=0. When this break is released, the function FACTORIAL returns its value of 120.

```
←PP FACTORIAL
(FACTORIAL
 [LAMBDA (N)
  (PROG ((M 1))
   LOOP (COND
        ((ZEROP N)
        (RETURN M)))
      (SETQ M (ITIMES M N))
      (SETQ N (SUB1 N))
      (GO LOOP])
FACTORIAL
←(BREAKIN FACTORIAL (AFTER LOOP) (ILESSP N 2]

:OK
(FACTORIAL)
((FACTORIAL) BROKEN)
:N
:OK
```

(FACTORIAL)

120

**—** 

Note: BREAK and TRACE can also be used on CLISP words which appear as CAR of form, e.g. FETCH, REPLACE, IF, FOR, DO, etc., even though these are not implemented as functions. For conditional breaking, the user can refer to the entire expression via the variable EXP, e.g. (BREAK (FOR (MEMB 'UNTIL EXP))).

#### (BREAKO FN WHEN COMS --- --)

[Function]

Sets up a break on the function *FN*; returns *FN*. If *FN* is not defined, returns (*FN* NOT DEFINED).

The value of WHEN, if non-NIL, should be an expression that is evaluated whenever FN is entered. If the value of the expression is non-NIL, a break is entered, otherwise the function simply called and returns without causing a break. This provides the means of conditionally breaking a function.

The value of COMS, if non-NIL, should be a list of break commands, that are interpreted and executed if a break occurs. (See the BRKCOMS argument to BREAK1, page 14.17.)

BREAKO sets up a break by doing the following: (1) it redefines FN as a call to BREAK1 (page 14.16), passing an equivalent definition of FN, WHEN, FN, and COMS as the BRKEXP, BRKWHEN, BRKFN, and BRKCOMS arguments to BREAK1; (2) it defines a GENSYM (page 2.10) with the original definition of FN, and puts it on the property list of FN under the property BROKEN; (3) it puts the form (BREAKO WHEN COMS) on the property list of FN under the property BRKINFO (for use in conjunction with REBREAK); and (4) it adds FN to the front of the list BROKENFNS.

If FN is non-atomic and of the form (FN1 IN FN2), BREAKO breaks every call to FN1 from within FN2. This is useful for breaking on a function that is called from many places, but where one is only interested in the call from a specific function, e.g., (RPLACA IN FOO), (PRINT IN FIE), etc. It is similar to BREAKIN described below, but can be performed even when FN2 is compiled or blockcompiled, whereas BREAKIN only works on interpreted functions. If FN1 is not found in FN2, BREAKO returns the value (FN1 NOT FOUND IN FN2).

**BREAKO** breaks one function *inside* another by first calling a function which changes the name of *FN1* wherever it appears inside of *FN2* to that of a new function, *FN1-IN-FN2*, which is initially given the same function definition as *FN1*. Then **BREAKO** proceeds to break on *FN1-IN-FN2* exactly as described above. In addition to breaking *FN1-IN-FN2* and adding *FN1-IN-FN2* to the list **BROKENFNS**, **BREAKO** adds *FN1* to the property value for the

property NAMESCHANGED on the property list of FN2 and puts (FN2.FN1) on the property list of FN1-IN-FN2 under the property ALIAS. This will enable UNBREAK to recognize what changes have been made and restore the function FN2 to its original state.

If FN is nonatomic and not of the above form, BREAKO is called for each member of FN using the same values for WHEN, COMS, and FILE. This distributivity permits the user to specify complicated break conditions on several functions. For example,

(BREAKO '(FOO1 ((PRINT PRIN1) IN (FOO2 FOO3)))

'(NEO X T)

'(EVAL ? = (Y Z) OK) )

will break on FOO1, PRINT-IN-FOO2, PRINT-IN-FOO3, PRIN1-IN-FOO2 and PRIN1-IN-FOO3.

If FN is non-atomic, the value of BREAKO is a list of the functions broken.

#### (BREAK X)

[NLambda NoSpread Function]

For each atomic argument, it performs (BREAKO ATOM T). For each list, it performs (APPLY 'BREAKO LIST). For example, (BREAK FOO1 (FOO2 (GREATERP N 5) (EVAL))) is equivalent to (BREAKO 'FOO1 T) and (BREAKO 'FOO2 '(GREATERP N 5) '(EVAL)).

#### (TRACE X)

[NLambda NoSpread Function]

For each atomic argument, it performs (BREAKO ATOM T '(TRACE ? = NIL GO)). The flag TRACE is checked for in BREAK1 and causes the message "FUNCTION:" to be printed instead of (FUNCTION BROKEN).

For each list argument, **CAR** is the function to be traced, and **CDR** the forms the user wishes to see, i.e., **TRACE** performs:

(BREAKO (CAR LIST) T (LIST 'TRACE '? = (CDR LIST) 'GO))

For example, (TRACE FOO1 (FOO2 Y)) will cause both FOO1 and FOO2 to be traced. All the arguments of FOO1 will be printed; only the value of Y will be printed for FOO2. In the special case that the user wants to see *only* the value, he can perform (TRACE (FUNCTION)). This sets up a break with commands (TRACE ? = (NIL) GO).

Note: the user can always call BREAK0 himself to obtain combination of options of BREAK1 not directly available with BREAK and TRACE. These two functions merely provide convenient ways of calling BREAK0, and will serve for most uses.

Note: BREAKO, BREAK, and TRACE print a warning if the user tries to modify a function on the list UNSAFE.TO.MODIFY.FNS (page 10.10).

BREAKIN enables the user to insert a break, i.e., a call to BREAK1 (page 14.16), at a specified location in the interpreted function FN. BREAKIN can be used to insert breaks before or after PROG labels, particular SETQ expressions, or even the evaluation of a variable. This is because BREAKIN operates by calling the editor and actually inserting a call to BREAK1 at a specified point inside of the function. If FN is a compiled function, BREAKIN returns (FN UNBREAKABLE) as its value.

WHEN should be an expression that is evaluated whenever the break is entered. If the value of the expression is non-NIL, a break is entered, otherwise the function simply called and returns without causing a break. This provides the means of creating a conditional break. Note: For BREAKIN, unlike BREAKO, if WHEN is NIL, it defaults to T.

COMS, if non-NIL, should be a list of break commands, that are interpreted and executed if a break occurs. (See the *BRKCONMS* argument to **BREAK1**, page 14.17.)

WHERE specifies where in the definition of FN the call to BREAK1 is to be inserted. WHERE should be a list of the form (BEFORE ...), (AFTER ...), or (AROUND ...). The user specifies where the break is to be inserted by a sequence of editor commands, preceded by one of the litatoms BEFORE, AFTER, or AROUND, which BREAKIN uses to determine what to do once the editor has found the specified point, i.e., put the call to BREAK1 BEFORE that point, AFTER that point, or AROUND that point. For example, (BEFORE COND) will insert a break before the first occurrence of COND, (AFTER COND 2 1) will insert a break after the predicate in the first COND clause, (AFTER BF (SETQ X &)) after the last place X is set. Note that (BEFORE TTY:) or (AFTER TTY:) permit the user to type in commands to the editor, locate the correct point, and verify it, and exit from the editor with OK. BREAKIN then inserts the break BEFORE, AFTER, or AROUND that point.

Note: A STOP command typed to TTY: produces the same effect as an unsuccessful edit command in the original specification, e.g., (BEFORE CONDD). In both cases, the editor aborts, and BREAKIN types (NOT FOUND).

If WHERE is (BEFORE ...) or (AFTER ...), the break expression is NIL, since the value of the break is irrelevant. For (AROUND ...), the break expression will be the indicated form. In this case, the user can use the EVAL command to evaluate that form, and examine its value, before allowing the computation to proceed. For example, if the user inserted a break after a COND predicate, e.g., (AFTER (EQUAL X Y)), he would be powerless to alter the flow of computation if the predicate were not true, since the break would not be reached. However, by breaking (AROUND

(EQUAL X Y)), he can evaluate the break expression, i.e., (EQUAL X Y), look at its value, and return something else if he wished.

If FN is interpreted, BREAKIN types SEARCHING... while it calls the editor. If the location specified by WHERE is not found, BREAKIN types (NOT FOUND) and exits. If it is found, BREAKIN puts T under the property BROKEN-IN and (WHERE WHEN COMS) under the the property BRKINFO on the property list of FN, and adds FN to the front of the list BROKENFNS.

Multiple break points, can be inserted with a single call to BREAKIN by using a list of the form ((BEFORE ...) ... (AROUND ...)) for WHERE. It is also possible to call BREAK or TRACE on a function which has been modified by BREAKIN, and conversely to BREAKIN a function which has been redefined by a call to BREAK or TRACE.

The message typed for a BREAKIN break is ((FN) BROKEN), where FN is the name of the function inside of which the break was inserted. Any error, or typing control-E, will cause the full identifying message to be printed, e.g., (FOO BROKEN AFTER COND 2 1).

A special check is made to avoid inserting a break inside of an expression headed by any member of the list NOBREAKS, initialized to (GO QUOTE \*), since this break would never be activated. For example, if (GO L) appears before the label L, BREAKIN (AFTER L) will not insert the break inside of the GO expression, but skip this occurrence of L and go on to the next L, in this case the label L. Similarly, for BEFORE or AFTER breaks, BREAKIN checks to make sure that the break is being inserted at a "safe" place. For example, if the user requests a break (AFTER X) in (PROG ... (SETQ X &) ...), the break will actually be inserted after (SETQ X &), and a message printed to this effect, e.g., BREAK INSERTED AFTER (SETQ X &).

#### (UNBREAK X)

[NLambda NoSpread Function]

**UNBREAK** takes an indefinite number of functions modified by **BREAK**, **TRACE**, or **BREAKIN** and restores them to their original state by calling **UNBREAKO**. Returns list of values of **UNBREAKO**.

(UNBREAK) will unbreak all functions on BROKENFNS, in reverse order. It first sets BRKINFOLST to NIL.

**(UNBREAK T)** unbreaks just the first function on **BROKENFNS**, i.e., the most recently broken function.

#### (UNBREAKO FN —)

[Function]

Restores FN to its original state. If FN was not broken, value is (NOT BROKEN) and no changes are made. If FN was modified by BREAKIN, UNBREAKIN is called to edit it back to its original state.

If FN was created from (FN1 IN FN2), (i.e., if it has a property ALIAS), the function in which FN appears is restored to its original state. All dummy functions that were created by the break are eliminated. Adds property value of BRKINFO to (front of) BRKINFOLST.

Note: (UNBREAKO '(FN1 IN FN2)) is allowed: UNBREAKO will operate on (FN1-IN-FN2) instead.

#### (UNBREAKIN FN)

[Function]

Performs the appropriate editing operations to eliminate all changes made by **BREAKIN**. *FN* may be either the name or definition of a function. Value is *FN*.

**UNBREAKIN** is automatically called by **UNBREAK** if *FN* has property **BROKEN-IN** with value **T** on its property list.

#### (REBREAK X)

[NLambda NoSpread Function]

Nlambda nospread function for rebreaking functions that were previously broken without having to respecify the break information. For each function on X, REBREAK searches BRKINFOLST for break(s) and performs the corresponding operation. Value is a list of values corresponding to calls to BREAKO or BREAKIN. If no information is found for a particular function, returns (FN - NO BREAK INFORMATION SAVED).

(REBREAK) rebreaks everything on BRKINFOLST, so (REBREAK) is the inverse of (UNBREAK).

(REBREAK T) rebreaks just the first break on BRKINFOLST, i.e., the function most recently unbroken.

#### (CHANGENAME FN FROM TO)

[Function]

Replaces all occurrences of FROM by TO in the definition of FN. If FN is defined by an expr definition, CHANGENAME performs (ESUBST TO FROM (GETD FN)) (see page 16.73). If FN is compiled, CHANGENAME searches the literals of FN (and all of its compiler generated subfunctions), replacing each occurrence of FROM with TO.

Note that *FROM* and *TO* do not have to be functions, e.g., they can be names of variables, or any other literals.

**CHANGENAME** returns *FN* if at least one instance of *FROM* was found, otherwise **NIL**.

#### (VIRGINFN FN FLG)

[Function]

The function that knows how to restore functions to their original state regardless of any amount of breaks, breakins, advising, compiling and saving exprs, etc. It is used by **PRETTYPRINT**, **DEFINE**, and the compiler.

If FLG = NIL, as for **PRETTYPRINT**, it does not modify the definition of FN in the process of producing a "clean" version of the definition; it works on a copy.

If FLG = T, as for the compiler and DEFINE, it physically restores the function to its original state, and prints the changes it is making, e.g., FOO UNBROKEN, FOO UNADVISED, FOO NAMES RESTORED, etc.

Returns the virgin function definition.

# 15.2 Advising

The operation of advising gives the user a way of modifying a function without necessarily knowing how the function works or even what it does. Advising consists of modifying the *interface* between functions as opposed to modifying the function definition itself, as in editing. BREAK, TRACE, and BREAKDOWN, are examples of the use of this technique: they each modify user functions by placing relevant computations between the function and the rest of the programming environment.

The principal advantage of advising, aside from its convenience, is that it allows the user to treat functions, his or someone else's, as "black boxes," and to modify them without concern for their contents or details of operations. For example, the user could modify SYSOUT to set SYSDATE to the time and date of creation by (ADVISE'SYSOUT'(SETQ SYSDATE (DATE))).

As with BREAK, advising works equally well on compiled and interpreted functions. Similarly, it is possible to effect a modification which only operates when a function is called from some other specified function, i.e., to modify the interface between two particular functions, instead of the interface between one function and the rest of the world. This latter feature is especially useful for changing the *internal* workings of a system function.

For example, suppose the user wanted TIME (page 22.8) to print the results of his measurements to the file FOO instead of the terminal. He could accomplish this by (ADVISE '((PRIN1 PRINT SPACES) IN TIME) 'BEFORE' (SETQQ U FOO)).

Note that advising PRIN1, PRINT, or SPACES directly would have affected all calls to these very frequently used function, whereas advising ((PRIN1 PRINT SPACES) IN TIME) affects just those calls to PRIN1, PRINT, and SPACES from TIME.

Advice can also be specified to operate after a function has been evaluated. The value of the body of the original function can be obtained from the variable !VALUE, as with BREAK1.

### 15.2.1 Implementation of Advising

After a function has been modified several times by ADVISE, it will look like:

```
(LAMBDA arguments
(PROG (!VALUE)
(SETQ !VALUE
(PROG NIL
advice1
. advice before
. advicen
(RETURN BODY)))
advice1
. advice after
. advicem
(RETURN !VALUE)))
```

where BODY is equivalent to the original definition. If FN was originally an expr definition, BODY is the body of the definition, otherwise a form using a GENSYM which is defined with the original definition.

Note that the structure of a function modified by ADVISE allows a piece of advice to bypass the original definition by using the function RETURN. For example, if (COND ((ATOM X) (RETURN Y))) were one of the pieces of advice BEFORE a function, and this function was entered with X atomic, Y would be returned as the value of the inner PROG, !VALUE would be set to Y, and control passed to the advice, if any, to be executed AFTER the function. If this same piece of advice appeared AFTER the function, Y would be returned as the value of the entire advised function.

The advice (COND ((ATOM X) (SETQ !VALUE Y))) AFTER the function would have a similar effect, but the rest of the advice AFTER the function would still be executed.

Note: Actually, ADVISE uses its own versions of PROG, SETQ, and RETURN, (called ADV-PROG, ADV-SETQ, and ADV-RETURN) in order to enable advising these functions.

#### 15.2.2 Advise Functions

**ADVISE** is a function of four arguments: *FN*, *WHEN*, *WHERE*, and *WHAT*. *FN* is the function to be modified by advising, *WHAT* is the modification, or piece of advice. *WHEN* is either **BEFORE**, **AFTER**, or **AROUND**, and indicates whether the advice is to operate **BEFORE**, **AFTER**, or **AROUND** the body of the function

definition. WHERE specifies exactly where in the list of advice the new advice is to be placed, e.g., FIRST, or (BEFORE PRINT) meaning before the advice containing PRINT, or (AFTER 3) meaning after the third piece of advice, or even (: TTY:). If WHERE is specified, ADVISE first checks to see if it is one of LAST, BOTTOM, END, FIRST, or TOP, and operates accordingly. Otherwise, it constructs an appropriate edit command and calls the editor to insert the advice at the corresponding location.

Both WHEN and WHERE are optional arguments, in the sense that they can be omitted in the call to ADVISE. In other words, ADVISE can be thought of as a function of two arguments (ADVISE FN WHAT), or a function of three arguments: (ADVISE FN WHEN WHAT), or a function of four arguments: (ADVISE FN WHEN WHERE WHAT). Note that the advice is always the last argument. If WHEN = NIL, BEFORE is used. If WHERE = NIL, LAST is used.

#### (ADVISE FN WHEN WHERE WHAT)

[Function]

FN is the function to be advised, WHEN = BEFORE, AFTER, or AROUND, WHERE specifies where in the advice list the advice is to be inserted, and WHAT is the piece of advice.

If FN is of the form (FN1 IN FN2), FN1 is changed to FN1-IN-FN2 throughout FN2, as with break, and then FN1-IN-FN2 is used in place of FN. If FN1 and/or FN2 are lists, they are distributed as with BREAK0, page 15.4.

If FN is broken, it is unbroken before advising.

If FN is not defined, an error is generated, NOT A FUNCTION.

If FN is being advised for the first time, i.e., if (GETP FN 'ADVISED) = NIL, a GENSYM is generated and stored on the property list of FN under the property ADVISED, and the GENSYM is defined with the original definition of FN. An appropriate expr definition is then created for FN, using private versions of PROG, SETQ, and RETURN, so that these functions can also be advised. Finally, FN is added to the (front of) ADVISEDFNS, so that (UNADVISE T) always unadvises the last function advised (see page 15.12).

If FN has been advised before, it is moved to the front of ADVISEDFNS.

If WHEN = BEFORE or AFTER, the advice is inserted in FN's definition either BEFORE or AFTER the original body of the function. Within that context, its position is determined by WHERE. If WHERE = LAST, BOTTOM, END, or NIL, the advice is added following all other advice, if any. If WHERE = FIRST or TOP, the advice is inserted as the first piece of advice. Otherwise, WHERE is treated as a command for the editor, similar to BREAKIN, e.g., (BEFORE 3), (AFTER PRINT).

If WHEN = AROUND, the body is substituted for \* in the advice, and the result becomes the new body, e.g., (ADVISE 'FOO 'AROUND '(RESETFORM (OUTPUT T) \*)). Note that if several pieces of AROUND advice are specified, earlier ones will be embedded inside later ones. The value of WHERE is ignored.

Finally (LIST WHEN WHERE WHAT) is added (by ADDPROP) to the value of property ADVICE on the property list of FN, so that a record of all the changes is available for subsequent use in readvising. Note that this property value is a list of the advice in order of calls to ADVISE, not necessarily in order of appearance of the advice in the definition of FN.

The value of ADVISE is FN.

If *FN* is non-atomic, every function in *FN* is advised with the same values (but copies) for *WHEN*, *WHERE*, and *WHAT*. In this case, **ADVISE** returns a list of individual functions.

Note: advised functions can be broken. However if a function is broken at the time it is advised, it is first unbroken. Similarly, advised functions can be edited, including their advice. **UNADVISE** will still restore the function to its unadvised state, but any changes to the body of the definition will survive. Since the advice stored on the property list is the same structure as the advice inserted in the function, editing of advice can be performed on either the function's definition or its property list.

#### (UNADVISE X)

#### [NLambda NoSpread Function]

An nlambda nospread like UNBREAK. It takes an indefinite number of functions and restores them to their original unadvised state, including removing the properties added by ADVISE. UNADVISE saves on the list ADVINFOLST enough information to allow restoring a function to its advised state using READVISE. ADVINFOLST and READVISE thus correspond to BRKINFOLST and REBREAK. If a function contains the property READVICE, UNADVISE moves the current value of the property ADVICE to READVICE.

(UNADVISE) unadvises all functions on ADVISEDFNS in reverse order, so that the most recently advised function is unadvised last. It first sets ADVINFOLST to NIL.

**(UNADVISE T)** unadvises the first function of **ADVISEDFNS**, i.e., the most recently advised function.

#### (READVISE X)

#### [NLambda NoSpread Function]

An nlambda nospread like **REBREAK** for restoring a function to its advised state without having to specify all the advise information. For each function on *X*, **READVISE** retrieves the advise information either from the property **READVICE** for that

function, or from ADVINFOLST, and performs the corresponding advise operation(s). In addition it stores this information on the property READVICE if not already there. If no information is found for a particular function, value is (FN - NO ADVICE SAVED).

(READVISE) readvises everything on ADVINFOLST.

(READVISE T) readvises the first function on ADVINFOLST, i.e., the function most recently unadvised.

A difference between ADVISE, UNADVISE, and READVISE versus BREAK, UNBREAK, and REBREAK, is that if a function is not rebroken between successive (UNBREAK)'s, its break information is forgotten. However, once READVISE is called on a function, that function's advice is permanently saved on its property list (under READVICE); subsequent calls to UNADVISE will not remove it. In fact, calls to UNADVISE update the property **READVICE** with the current value of the property **ADVICE**, so that the sequence READVISE, ADVISE, UNADVISE causes the augmented advice to become permanent. Note that the sequence READVISE, ADVISE, READVISE removes "intermediate advice" by restoring the function to its earlier state.

#### (ADVISEDUMP X FLG)

[Function]

Used by PRETTYDEF when given a command of the form (ADVISE ...) or (ADVICE ...). If FLG = T, ADVISEDUMP writes both a DEFLIST and a READVISE (this corresponds to (ADVISE ...)). If FLG = NIL, only the DEFLIST is written (this corresponds to (ADVICE ...)). In either case, ADVISEDUMP copies the advise information to the property READVICE, thereby making it "permanent" as described above.

TOC.2

Many important objects such as function definitions, property lists, and variable values are represented as list structures. The Interlisp-D environment includes a list structure editor to allow the user to rapidly and conveniently modify list structures.

The list structure editor is most often used to edit function definitions. Editing function definitions "in core" is a facility not offered by many lisp systems, where typically the user edits external text files containing function definitions, and then loads them into the environment. In Interlisp, function definitions are edited in the environment, and written to an external file using the file package (page 17.1), which provides a complex set of tools for managing function definitions.

Early implementations of Interlisp using primitive terminals offered a teletype-oriented editor, which included a large set of cryptic commands for printing different parts of a list structure, searching a list, replacing elements, etc. Interlisp-D includes an extended, display-oriented version of the teletype list structure editor, called DEdit. The teletype editor is still available, as it offers a facility for doing complex modifications of program structure under program control. For example, BREAKIN (page 15.6) calls the teletype editor to insert a function break within the body of a function. DEdit also provides facilities for using the complex teletype editor commands from within DEdit. By calling the function EDITMODE (page 16.4) it is possible to set the "default editor" (TELETYPE or DISPLAY) called by Masterscope, the break package, etc.

This chapter documents both DEdit and the teletype list structure editor (sometimes referred to as "Edit"). The first part documents DEdit, the most commonly used editor of the two. Then, there are a large number of sections describing the commands of the older teletype editor. Most users will only need to reference the DEdit documentation.

#### 16.1 **DEdit**

DEdit is a structure oriented, modeless, display based editor for objects represented as list structures, such as functions, property

lists, data values, etc. DEdit is an integral part of the standard Interlisp-D environment.

DEdit is designed to be the user's primary editor for programs and data. To that end, it has incorporated the interfaces of the (older) teletype oriented Interlisp editor so the two can be used interchangeably. In addition, the full power of the teletype editor, and indeed the full Interlisp system itself, is easily accessible from within DEdit.

DEdit is structure, rather than character, oriented to facilitate selecting and operating on pieces of structure as objects in their own right, rather than as collections of characters. However, for the occasional situation when character oriented editing is appropriate, DEdit provides access to the Interlisp-D text editing facilities. DEdit is modeless, in that all commands operate on previously selected arguments, rather than causing the behavior of the interface to change during argument specification.

# 16.1.1 Calling DEdit

DEdit is normally called using the following functions:

#### (DF FN NEW?)

#### [NLambda NoSpread Function]

Calls DEdit on the definition of the function FN. DF handles exceptional cases (the function is broken or advised, the expr definition is on the property list, the function needs to be loaded from a file, etc.) the same as EDITF (see page 16.68).

If DF is called on a name with no function definition, the user is prompted with "No FNS defn for FN. Do you wish to edit a dummy defn?". If the user confirms by typing Yes, a "blank" definition (stored on the variable DUMMY-EDIT-FUNCTION-BODY) is displayed in the Dedit window. If any changes are made, on exit from the editor, the definition will be installed as the name's function definition. Exiting the editor with the STOP command will prevent any changes to the function definition.

If **DF** is called with a second arg of **NEW**, as in **(DF** *FNNAME* **NEW)**, a blank definition will be edited whether the function already has a definition or not.

#### (DV VAR)

#### [NLambda NoSpread Function]

Calls DEdit on the value of the variable VAR.

#### (DP NAME PROP)

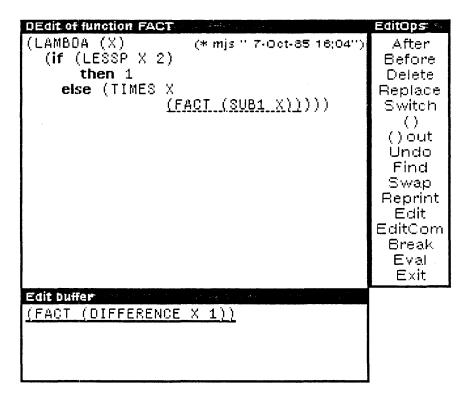

#### [NLambda NoSpread Function]

Calls DEdit on the property *PROP* of the atom *NAME*. If *PROP* is not given, the whole property list of *NAME* is edited.

[NLambda NoSpread Function]

Calls DEdit on the file package commands (or filecoms, see page 17.32) for the file *FILE*.

When DEdit is called for the first time, it prompts for an edit window, which is preserved and reused for later DEdits, and pretty prints the expression to be edited therein. (Note: The DEdit pretty printer ignores user PRETTYPRINTMACROS because they do not provide enough structural information during printing to enable selection.) The expression being edited can be scrolled by using a standard Interlisp-D scroll bar on the left edge of the window. DEdit adds an edit command menu, which remains active throughout the edit, on the right edge of the edit window. If anything is typed by the user, an "edit buffer" window is positioned below the edit window. Below is a picture of a Dedit window, displaying the function definition for FACT:

While Dedit is running, it yields control so that background activities, such as mouse commands in other windows, continue to be performed.

(RESETDEDIT)

[Function]

Completely reinitializes DEdit. Closes all DEdit windows, so that the user must specify the window the next time DEdit is envoked. **RESETDEDIT** is also used to make DEdit recognize the new values

of variables such as **DEDITTYPEINCOMS** (page 16.12), when the user changes them.

DEdit is normally installed as the default editor for all editing operations, including those invoked by other subsystems, such as the Programmer's Assistant and Masterscope. DEdit provides functions EF, EV and EP (analogous to the corresponding Dx functions) for conveniently accessing the teletype editor from within a DEdit context, e.g. from under a call to DEdit or if DEdit is installed as the default editor.

The default editor may be set with EDITMODE:

### (EDITMODE NEWMODE)

[Function]

If **NEWMODE** is non-**NIL**, sets the default editor to be DEdit (if **NEWMODE** is **DISPLAY**), or the teletype editor (if **NEWMODE** is **TELETYPE**). Returns the previous setting.

DEdit operates by providing an alternative, plug-compatible definition of EDITL (DEDITL). The normal user entries operate by redefining EDITL and then calling the corresponding teletype editor function (i.e., DF calls EDITF etc). Thus, the normal teletype editor file package, spelling correction, etc. behavior is obtained.

If teletype editor commands are specified in a call to DEDITL (e.g., in calls to the editor from Masterscope), DEDITL will pass those commands to EDITL, after having placed a TTY: entry on EDITMACROS which will cause DEdit to be invoked if any interaction with the user is called for. In this way, automatic edits can be made completely under program control, yet DEdit's interactive interface is available for direct user interaction.

# 16.1.2 Selecting Objects and Lists

Selection in a DEdit window is as follows: the LEFT button selects the object being directly pointed at; the MIDDLE button selects the containing list; and the RIGHT button extends the current selection to the lowest common ancestor of that selection and the current position. The only things that may be pointed at are atomic objects (literal atoms, numbers, etc) and parentheses, which are considered to represent the list they delimit. White space is not selectable or editable.

When a selection is made, it is pushed on a selection stack which will be the source of operands for DEdit commands. As each new selection pushes down the selections made before it, this stack can grow arbitrarily deep, so only the top two selections on the stack are highlighted on the screen. This highlighting is done by

underscoring the topmost (most recent) selection with a solid black line and the second topmost selection with a dashed line. The patterns used were chosen so that their overlappings would be both visible and distinct, since selecting a sub-part of another selection is quite common. For example, in the picture below, the last selection is the list (FACT (SUB1 X)), and the previous selection is the single litatom SUB1:

```
DEdit of function FACT

(LAMBOA (X) (* mjs " 7-0ct-85 16;04")

(if (LESSP X 2)

then 1

else (TIMES X

(FACT (SUB1 X))))
```

Because one can invoke DEdit recursively, there may be several DEdit windows active on the screen at once. This is often useful when transferring material from one object to another (as when reallocating functionality within a set of programs). Selections may be made in any active DEdit window, in any order. When there is more than one DEdit window, the edit command menu (and the type-in buffer, see below) will attach itself to the most recently opened (or current) DEdit window.

# 16.1.3 Typing Characters to DEdit

Characters may be typed at the keyboard at any time. This will create a type-in buffer window which will position itself under the current DEdit window and do a LISPXREAD (which must be terminated by a right parenthesis or a return) from the keyboard. During the read, any character editing subsystem (such as TTYIN) that is loaded can be used to do character level editing on the typein. When the read is complete, the typein will become the current selection (top of stack) and be available as an operand for the next command. Once the read is complete, objects displayed in the type-in buffer can be selected from, scrolled, or even edited, just like those in the main window.

One can also give some editing commands directly into the typein buffer. Typing control-Z will interpret the rest of the line as a teletype editor command which will be interpreted when the line is closed. Likewise, "control-S *OLD NEW*" will substitute *NEW* for *OLD* and "control-F X" will find the next occurrence of X.

# 16.1.4 Copy-Selection

Often, significant pieces of what one wishes to type can be found in an active DEdit window. To aid in transferring the

keystrokes that these objects represent into the typein buffer, DEdit supports copy-selection. Whenever a selection is made in the DEdit window with either shift key down (or the COPY key on the Xerox 1108), the selection made is not pushed on the selection stack, but is instead *unread* into the keyboard input (and hence shows up in the typein buffer). A characteristically different highlighting is used to indicate when copy selection (as opposed to normal selection) is taking place.

Note that copy-selection remains active even when DEdit is not. Thus one can unread particularly choice pieces of text from DEdit windows into the typescript window.

### 16.1.5 DEdit Commands

A DEdit command is invoked by selecting an item from the edit command menu. This can be done either directly, using the LEFT mouse button in the usual way, or by selecting a subcommand. Subcommands are less frequently used commands than those on the main edit command menu and are grouped together in submenus "under" the command on the main menu to which they are most closely related. For example, the teletype editor defines six commands for adding and removing parentheses (defined in terms of transformations on the underlying list structure). Of these six commands, only two (inserting and removing parentheses as a pair) are commonly used, so DEdit provides the other four as subcommands of the common two. The subcommands of a command are accessed by selecting the command from the commands menu with the MIDDLE button. This will bring up a menu of the subcommand options from which a choice can be made. Subcommands are flagged in the list below with the name of the top level command of which they are options.

If one has a large DEdit window, or several DEdit windows active at once, the edit command window may be far away from the area of the screen in which one is operating. To solve this problem, the DEdit command window is a "snuggle up" menu. Whenever the TAB key is depressed, the command window will move over to the current cursor position and stay there as long as either the TAB key remains down or the cursor is in the command window. Thus, one can "pull" the command window over, slide the cursor into it and then release the TAB key (or not) while one makes a command selection in the normal way. This eliminates a great deal of mouse movement.

Whenever a change is made, the prettyprinter reprints until the printing stablizes. As the standard pretty print algorithm is used and as it leaves no information behind on how it makes its choices, this is a somewhat heuristic process. The Reprint

command can be used to tidy the result up if it is not, in fact, "pretty".

All commands take their operands from the selection stack, and may push a result back on. In general, the rule is to select *target* selections first and *source* selections second. Thus, a Replace command is done by selecting the thing to be replaced, selecting (or typing) the new material, and then buttoning the Replace command in the command menu. Using *TOP* to denote the topmost (most recent) element of the stack and *NXT* the second element, the DEdit commands are:

After	[DEdit Command]
	Inserts a copy of <i>TOP</i> after <i>NXT</i> .
Before	[DEdit Command]
	Inserts a copy of <i>TOP</i> before <i>NXT</i> .
Delete	[DEdit Command]
	Deletes <i>TOP</i> from the structure being edited. (A copy of) <i>TOP</i> remains on the stack and will appear, selected, in the edit buffer.
Replace	[DEdit Command]
	Replaces <i>NXT</i> with a copy of <i>TOP</i> obtained by substituting a copy of <i>NXT</i> wherever the value of the atom <b>EDITEMBEDTOKEN</b> (initially, the & character) appears in <i>TOP</i> . This provides a facility like the <b>MBD</b> edit command (page 16.36), see Idioms below.
Switch	
2Mittu	[DEdit Command]  Exchanges TOP and NXT in the structure being edited.
0	[DEdit Command]
	Puts parentheses around <i>TOP</i> and <i>NXT</i> (which can, of course, be the same element).
(in	[DEdit Command]
	Subcommand of (). Inserts ( before <i>TOP</i> (like the <b>LI</b> Edit command, page 16.41)
) in	[DEdit Command]
	Subcommand of (). Inserts ) after TOP (like the RI Edit command, page 16.41)
() out	[DEdit Command]
	Removes parentheses from TOP.

( out	[DEdit Command]
	Subcommand of () out. Removes ( from before <i>TOP</i> (like the LO Edit command, page 16.41)
) out	[DEdit Command]
	Subcommand of () out. Removes ) from after <i>TOP</i> (like the RO Edit command, page 16.41)
Undo	[DEdit Command]
	Undoes last command.
!Undo	[DEdit Command]
	Subcommand of <b>Undo</b> . Undoes all changes since the start of this call on DEdit. This command can be undone.
?Undo	[DEdit Command]
&Undo	[DEdit Command]
	Subcommands of <b>Undo</b> . Allows selective undoing of other than the last command. Both of these commands bring up a menu of all the commands issued during this call on DEdit. When the user selects an item from this menu, the corresponding command (and if <b>&amp;Undo</b> , all commands since that point) will be undone.
Find	[DEdit Command]
	Selects, in place of <i>TOP</i> , the first place after <i>TOP</i> which matches <i>NXT</i> . Uses the Edit subsystem's search routine, so supports the full wildcarding conventions of Edit.
Swap	[DEdit Command]
	Exchanges <i>TOP</i> and <i>NXT</i> on the stack, i.e. the stack is changed, the structure being edited isn't.
	The following set of commands are grouped together as subcommands of <b>Swap</b> because they all affect the stack and the selections, rather than the structure being edited.
Center	[DEdit Command]
	Subcommand of Swap. Scrolls until TOP is visible in its window.
Clear	[DEdit Command]
	Subcommand of Swap. Discards all selections (i.e., "clears" the stack).

Сору	[DEdit Command]
	Subcommand of Swap. Puts a copy of <i>TOP</i> into the edit buffer
	and makes it the new <i>TOP</i> .
Рор	[DEdit Command
	Subcommand of Swap. Pops TOP off the selection stack.
Reprint	Reprints <i>TOP</i> . [DEdit Command
Edit	[DEdit Command
	Runs DEdit on the definition of the atom TOP (or CAR of list TOP). Uses TYPESOF to determine what definitions exist for TOP and, if there is more than one, asks the user, via menu, which one to use. If TOP is defined and is a non-list, calls INSPECT on that value. Edit also has a variety of subcommands which allow choice of editor (DEdit, TTYEdit, etc.) and whether to invoke that editor on the definition of TOP or the form itself.
	Note: DEdit caches each subordinate edit window in the window from which it was entered, for as long as the higher window is active. Thus, multiple DEdit commands do not incur the cost of repeatedly allocating a new window.
EditCom	[DEdit Command]
	Allows one to run arbitrary Edit commands on the structure being DEdited (there are far too many of these for them all to appear on the main menu). TOP should be an Edit command, which will be applied to NXT as the current Edit expression. On return to DEdit, the (possibly changed) current Edit expression will be selected as the new TOP. Thus, selecting some expression typing (R FOO BAZ), and buttoning EditCom will cause FOO to be replaced with BAZ in the expression selected.
	In addition, a variety of common Edit commands are available as subcommands of EditCom. Currently, these include ? = , GETD, CL, DW, REPACK, CAP, LOWER, and RAISE.
Break	[DEdit Command]
	Does a <b>BREAKIN AROUND</b> the current expression <i>TOP.</i> (See page 15.6.)
Eval	[DEdit Command]
	Evaluates <i>TOP</i> , whose value is pushed onto the stack in place of <i>TOP</i> , and which will therefore appear, selected, in the edit buffer.

Exit	[DEdit Command]
	Exits from DEdit (equivalent to Edit <b>OK</b> , page 16.49).
ОК	[DEdit Command]
Stop	[DEdit Command]
	Subcommands of Exit. OK exits without an error; STOP exits with an error. Equivalent to the Edit commands with the same names.

## 16.1.6 Multiple Commands

It is occasionally useful to be able to give several commands at once - either because one thinks of them as a unit or because the intervening reprettyprinting is distracting. The stack architecture of DEdit makes such multiple commands easy to construct - one just pushes whatever arguments are required for the complete suite of commands one has in mind. Multiple commands are specified by holding down the CONTROL key during command selection. As long as the CONTROL key is down, commands selected will not be executed, but merely saved on a list. Finally, when a command is selected without the CONTROL key down, the command sequence is terminated with that command being the last one in the sequence.

One rarely constructs long sequences of commands in this fashion, because the feedback of being able to inspect the intermediate results is usually worthwhile. Typically, just two or three step idioms are composed in this fashion. Some common examples are given in the next section.

### 16.1.7 DEdit Idioms

As with any interactive system, there are certain common idioms on which experienced users depend heavily. Not only is discovering the idioms of a new system tiresome, but in places the designer may have assumed familiarity with one or more of them, so not knowing them can make life quite unbearable. In the case of DEdit, many of these idioms concern easy ways to achieve the effects of specific commands from the Edit system, with which many users are already familiar. The DEdit idioms described below are the result of the experience of the early users of the system and are by no means exhaustive. In addition to those that each user will develop to fit his or her own particular style, there are many more to be discovered and you are encouraged to share your discoveries.

Because of the novel argument specification technique (postfix; target first) many of the DEdit idioms are very simple, but opaque until one has absorbed the "target-source-command" way of looking at the world. Thus, one selects where typein is to go before touching the keyboard. After typing, the target will be selected second and the typein selected on top, so that an After, Before or Replace will have the desired effect. If the order is switched, the command will try to change the typein (which may or may not succeed), or will require tiresome Swapping or reselection. Although this discipline seems strange at first, it comes easily with practice.

Segment selection and manipulation are handled in DEdit by first making them into a sublist, so they can be handled in the usual way. Thus, if one wants to remove the three elements between A and E in the list (A B C D E), one selects B, then D (either order), then makes them into a sublist with the "()" command (pronounced "both in"). This will leave the sublist (B C D) selected, so a subsequent Delete will remove it. This can be issued as a single "(); Delete" command using multiple command selection, as described above, in which case the intermediate state of (A (B C D) E) will not show on the screen.

Inserting a segment proceeds in a similar fashion. Once the location of the insertion is selected, the segment to be inserted is typed as a list (if it is a list of atoms, they can be typed without parentheses and the READ will make them into a list, as one would expect). Then, the command sequence "After (or Before or Replace); () out" (given either as a multiple command or as two separate commands) will insert the typein and splice it in by removing its parentheses.

Moving an expression to another place in the structure being edited is easily accomplished by a delete followed by an insert. Select the location where the moved expression is to go to; select the expression to be moved; then give the command sequence "Delete; After (or Before or Replace)". The expression will first be deleted into the edit buffer where it will remain selected. The subsequent insertion will insert it back into the structure at the selected location.

Embedding and extracting are done with the Replace command. Extraction is simply a special case of replacing something with a subpiece of itself: select the thing to be replaced; select the subpart that is to replace it; Replace. Embedding also uses Replace, in conjunction with the "embed token" (the value of EDITEMBEDTOKEN, initially the single character atom &). Thus, to embed some expression in a PROG, select the expression; type "(PROG VARSLST &)"; Replace.

Switch can also be used to generate a whole variety of complex moves and embeds. For example, switching an expression with

LIST STRUCTURE EDITOR 16.11

typein not only replaces that expression with the typein, but provides a copy of the expression in the buffer, from where it can be edited or moved to somewhere else.

Finally, one can exploit the stack structure on selections to queue multiple arguments for a sequence of commands. Thus, to replace several expressions by one common replacement, select each of the expressions to be replaced (any number), then the replacing expression. Now hit the Replace command as many times as there are replacements to be done. Each Replace will pop one selection off the stack, leaving the most recently replaced expression selected. As the latter is now a copy of the original source, the next Replace will have the desired effect, and so on.

## 16.1.8 DEdit Parameters

There are several global variables that can be used to affect various aspects of DEdit's operation. Although most have been alluded to above, they are summarized here for reference.

#### **EDITEMBEDTOKEN**

[Variable]

Initially &. Used in both DEdit and the teletype editor to indicate the special atom used as the "embed token".

#### **DEditLinger**

[Variable]

Initially T. The default behavior of the topmost DEdit window is to remain active on the screen when exited. This is occasionally inconvenient for programs that call DEdit directly, so it can be made to close automatically when exited by setting this variable to NIL.

### **DEDITTYPEINCOMS**

[Variable]

Defines the control characters recognized as commands during DEdit typein. The elements of this list are of the form (LETTER COMMANDNAME FN), where LETTER is the alphabetic corresponding to the control character desired (e.g., A for control-A), COMMANDNAME is a litatom used both as a prompt and internal tag, and FN is a function applied to the expressions typed as arguments to the command. See the current value of DEDITTYPEINCOMS for examples. DEDITTYPEINCOMS is only accessed when DEdit is initialized, so DEdit should be reinitialized with RESETDEDIT (page 16.3) if it is changed.

### **DT.EDITMACROS**

[Variable]

Defines the behavior of the Edit command when invoked on a form that is not a list or litatom, thus telling DEdit how to edit

instances of certain datatypes. DT.EDITMACROS is an association list keyed by datatype name; entries are of the form (DATATYPE MAKESOURCEFN INSTALLEDITFN). When told to Edit an object of type DATATYPE, DEdit calls MAKESOURCEFN with the object as its argument. MAKESOURCEFN can either do the editing itself, in which case it should return NIL, or it should "destructure" the object into an editable list and return that list. In the latter case, DEdit is then invoked recursively on the list; when that edit is finished, DEdit calls INSTALLEDITFN with two arguments, the original object and the edited list. If INSTALLEDITFN causes an error, the recursive Dedit is invoked again, and the process repeats until the user either exits the lower editor with STOP, or exits with an expression that INSTALLEDITFN accepts.

For example, suppose the user has a datatype declared by (DATATYPE FOO (NAME AGE SEX)). To make instances of FOO editable, an entry (FOO DESTRUCTUREFOO INSTALLFOO) is added to DT.EDITMACROS, where the functions are defined by

(DESTRUCTUREFOO (OBJECT) (LIST (fetch NAME of OBJECT) (fetch AGE of OBJECT) (fetch SEX of OBJECT)))

(INSTALLFOO (OBJECT CONTENTS)

(if (EQLENGTH CONTENTS 3)

then (replace NAME of OBJECT with (CAR CONTENTS))

(replace AGE of OBJECT with (CADR CONTENTS))

(replace SEX of OBJECT with (CADDR CONTENTS))

else (ERROR "Wrong number of fields for FOO" CONTENTS)))

# 16.2 Local Attention-Changing Commands

This section describes commands that change the current expression (i.e., change the edit chain) thereby "shifting the editor's attention." These commands depend only on the structure of the edit chain, as compared to the search commands (presented later), which search the contents of the structure.

UP

[Editor Command]

**UP** modifies the edit chain so that the old current expression (i.e., the one at the time **UP** was called) is the first element in the new current expression. If the current expression is the first element in the next higher expression **UP** simply does a **0**. Otherwise **UP** adds the corresponding tail to the edit chain.

If a P command would cause the editor to type ... before typing the current expression, ie., the current expression is a tail of the next higher expression, UP has no effect.

For Example:

```
*PP
(COND ((NULL X) (RETURN Y)))
*1 P
COND
*UPP
(COND (& &))
*-1 P
((NULL X) (RETURN Y))
*UPP
... ((NULL X) (RETURN Y))
*UPP
... ((NULL X) (RETURN Y)))
*F NULL P
(NULL X)
*UPP
((NULL X) (RETURN Y))
*UP P
... ((NULL X) (RETURN Y)))
```

The execution of UP is straightforward, except in those cases where the current expression appears more than once in the next higher expression. For example, if the current expression is (A NIL B NIL C NIL) and the user performs 4 followed by UP, the current expression should then be ... NIL C NIL). UP can determine which tail is the correct one because the commands that descend save the last tail on an internal editor variable, LASTAIL. Thus after the 4 command is executed, LASTAIL is (NIL C NIL). When UP is called, it first determines if the current expression is a tail of the next higher expression. If it is, UP is UP finished. Otherwise, computes (MEMB CURRENT-EXPRESSION NEXT-HIGHER-EXPRESSION) to obtain a tail beginning with the current expression. The current expression should always be either a tail or an element of the next higher expression. If it is neither, for example the user has directly (and incorrectly) manipulated the edit chain, UP generates an error. If there are no other instances of the current expression in the next higher expression, this tail is the correct one. Otherwise UP uses LASTAIL to select the correct tail.

Occasionally the user can get the edit chain into a state where LASTAIL cannot resolve the ambiguity, for example if there were two non-atomic structures in the same expression that were EQ, and the user descended more than one level into one of them and then tried to come back out using UP. In this case, UP prints LOCATION UNCERTAIN and generates an error. Of course, we

could have solved this problem completely in our implementation by saving at each descent both elements and tails. However, this would be a costly solution to a situation that arises infrequently, and when it does, has no detrimental effects. The LASTAIL solution is cheap and resolves almost all of the ambiguities.

### N(N>=1)

### [Editor Command]

Adds the Nth element of the current expression to the front of the edit chain, thereby making it be the new current expression. Sets LASTAIL for use by UP. Generates an error if the current expression is not a list that contains at least N elements.

### -N(N>=1)

### [Editor Command]

Adds the Nth element from the end of the current expression to the front of the edit chain, thereby making it be the new current expression. Sets LASTAIL for use by UP. Generates an error if the current expression is not a list that contains at least N elements.

#### 0

#### [Editor Command]

Sets the edit chain to CDR of the edit chain, thereby making the next higher expression be the new current expression. Generates an error if there is no higher expression, i.e., CDR of edit chain is NIL.

Note that 0 usually corresponds to going back to the next higher left parenthesis, but not always. For example:

\*P

(ABCDEFB)

\*3 UP P

... C D E F G)

\*3 UP P

... E F G)

\*0 P

... CDEFG)

If the intention is to go back to the next higher left parenthesis, regardless of any intervening tails, the command !0 can be used.

!0

#### [Editor Command]

Does repeated 0's until it reaches a point where the current expression is *not* a tail of the next higher expression, i.e., always goes back to the next higher left parenthesis.

<b>↑</b>	[Editor Command]
	Sets the edit chain to LAST of edit chain, thereby making the top level expression be the current expression. Never generates an error.
	enor.
NX	[Editor Command]
	Effectively does an <b>UP</b> followed by a <b>2</b> , thereby making the current expression be the next expression. Generates an error if the current expression is the last one in a list. (However, !NX described below will handle this case.)
вк	[Editor Command]
	Makes the current expression be the previous expression in the next higher expression. Generates an error if the current expression is the first expression in a list.
	For example,
	*PP (COND ((NULL X) (RETURN Y)))  *F RETURN P (RETURN Y)
	*BK P (NULL X)
	Both <b>NX</b> and <b>BK</b> operate by performing a !0 followed by an appropriate number, i.e., there won't be an extra tail above the new current expression, as there would be if <b>NX</b> operated by performing an <b>UP</b> followed by a 2.
(NX N)	[Editor Command]
	(N > = 1) Equivalent to $N$ NX commands, except if an error occurs, the edit chain is not changed.
(BK N)	[Editor Command]
<u> </u>	(N > = 1) Equivalent to $N$ <b>BK</b> commands, except if an error occurs, the edit chain is not changed.
	Note: (NX -N) is equivalent to (BK N), and vice versa.
!NX	[Editor Command]
	level, i.e., goes through any number of right parentheses to get to the next expression. For example:
	*PP (PROG ((L L) (UF L))

```
LP (COND
    ((NULL (SETQ L (CDR L)))
     (ERROR!))
    ([NULL (CDR (FMEMB (CAR L) (CADR L]
     (GO LP)))
  (EDITCOM (QUOTE NX))
  (SETQ UNFIND UF)
  (RETURN L))
*F CDR P
(CDR L)
*NX
NX ?
*!NXP
(ERROR!)
*!NXP
((NULL &) (GO LP))
*!NXP
(EDITCOM (QUOTE NX))
```

!NX operates by doing 0's until it reaches a stage where the current expression is *not* the last expression in the next higher expression, and then does a NX. Thus !NX always goes through at least one unmatched right parenthesis, and the new current expression is always on a different level, i.e., !NX and NX always produce different results. For example using the previous current expression:

```
*F CAR P
(CAR L)
*!NX P
(GO LP)
*\P P
(CAR L)
*NX P
(CADR L)
```

(NTH N)

[Editor Command]

( $N^-=0$ ) Equivalent to N followed by UP, i.e., causes the list starting with the Nth element of the current expression (or Nth from the end if N < 0) to become the current expression. Causes an error if current expression does not have at least N elements.

(NTH 1) is a no-op, as is (NTH -L) where L is the length of the current expression.

line-feed	[Editor Command]
	Moves to the "next" expression and prints it, i.e. performs a NX if possible, otherwise performs a !NX. (The latter case is indicated by first printing ">".)
Control-X	[Editor Command]
	Control-X moves to the "previous" thing and then prints it, i.e. performs a BK if possible, otherwise a !0 followed by a BK.
Control-Z	[Editor Command]
	Control-Z moves to the last expression and prints it, i.e. does -1 followed by P.
	Line-feed, control-X, and control-Z are implemented as immediate read macros; as soon as they are read, they abort the current printout. They thus provide a convenient way of moving around in the editor. In order to facilitate using different control characters for those macros, the function SETTERMCHARS is

## 16.3 Commands That Search

All of the editor commands that search use the same pattern matching routine (the function **EDIT4E**, page 16.72). We will therefore begin our discussion of searching by describing the pattern match mechanism. A pattern *PAT* matches with *X* if any of the following conditions are true:

- (1) If PAT is **EQ** to X.
- (2) If PAT is &.
- (3) If PAT is a number and EQP to X.

provided (see page 16.75).

- (4) If PAT is a string and (STREQUAL PAT X) is true.
- (5) If (CAR PAT) is the atom \*ANY\*, (CDR PAT) is a list of patterns, and one of the patterns on (CDR PAT) matches X.
- (6) If PAT is a literal atom or string containing one or more \$s (escapes), each \$ can match an indefinite number (including 0) of contiguous characters in the atom or string X, e.g., VER\$ matches both VERYLONGATOM and "VERYLONGSTRING" as do \$LONG\$ (but not \$LONG), and \$V\$L\$T\$. Note: the litatom \$ (escape) matches only with itself.
- (7) If PAT is a literal atom or string ending in \$\$ (escape, escape), PAT matches with the atom or string X if it is "close" to PAT, in the

sense used by the spelling corrector (page 20.15). E.g. CONSS\$\$ matches with CONS, CNONC\$\$ with NCONC or NCONC1.

The pattern matching routine always types a message of the form = MATCHING-ITEM to inform the user of the object matched by a pattern of the above two types, unless EDITQUIETFLG = T. For example, if VER\$ matches VERYLONGATOM, the editor would print = VERYLONGATOM.

(8) If (CAR PAT) is the atom --, PAT matches X if (CDR PAT) matches with some tail of X. For example, (A -- (&)) will match with (A B C (D)), but not (A B C D), or (A B C (D) E). However, note that (A -- (&) --) will match with (A B C (D) E). In other words, -- can match any interior segment of a list.

If (CDR PAT) = NIL, i.e., PAT = (--), then it matches any tail of a list. Therefore, (A --) matches (A), (A B C) and (A . B).

(9) If (CAR PAT) is the atom = =, PAT matches X if and only if (CDR PAT) is EQ to X.

This pattern is for use by programs that call the editor as a subroutine, since any non-atomic expression in a command *typed* in by the user obviously cannot be **EQ** to already existing structure.

- (10) If (CADR PAT) is the atom .. (two periods), PAT matches X if (CAR PAT) matches (CAR X) and (CDDR PAT) is contained in X, as described on page 16.27.
- (11) Otherwise if X is a list, PAT matches X if (CAR PAT) matches (CAR X), and (CDR PAT) matches (CDR X).

When the editor is searching, the pattern matching routine is called to match with *elements* in the structure, unless the pattern begins with ... (three periods), in which case CDR of the pattern is matched against proper tails in the structure. Thus,

```
*P
(A B C (B C))
*F (B --)
*P
(B C)
*0 F (... B --)
*P
... B C (B C))
```

Matching is also attempted with atomic tails (except for NIL). Thus,

```
*P
(A (B . C))
*F C
*P
.... C)
```

Although the current expression is the atom C after the final command, it is printed as .... C) to alert the user to the fact that C is a tail, not an element. Note that the pattern C will match with either instance of C in (A C (B . C)), whereas (.... C) will match only the second C. The pattern NIL will only match with NIL as an element, i.e., it will not match in (A B), even though CDDR of (A B) is NIL. However, (.... NIL) (or equivalently (...)) may be used to specify a NIL tail, e.g., (.... NIL) will match with CDR of the third subexpression of ((A . B) (C . D) (E)).

## 16.3.1 Search Algorithm

Searching begins with the current expression and proceeds in print order. Searching usually means find the next instance of this pattern, and consequently a match is not attempted that would leave the edit chain unchanged. At each step, the pattern is matched against the next element in the expression currently being searched, unless the pattern begins with ... (three periods) in which case it is matched against the next tail of the expression.

If the match is not successful, the search operation is recursive first in the CAR direction, and then in the CDR direction, i.e., if the element under examination is a list, the search descends into that list before attempting to match with other elements (or tails) at the same level. Note: A find command of the form (F PATTERN NIL) will only attempts matches at the top level of the current expression, i.e., it does not descend into elements, or ascend to higher expressions.

However, at no point is the total recursive depth of the search (sum of number of CARs and CDRs descended into) allowed to exceed the value of the variable MAXLEVEL. At that point, the search of that element or tail is abandoned, exactly as though the element or tail had been completely searched without finding a match, and the search continues with the element or tail for which the recursive depth is below MAXLEVEL. This feature is designed to enable the user to search circular list structures (by setting MAXLEVEL small), as well as protecting him from accidentally encountering a circular list structure in the course of normal editing. MAXLEVEL can also be set to NIL, which is equivalent to infinity. MAXLEVEL is initially set to 300.

If a successful match is not found in the current expression, the search automatically ascends to the next higher expression, and continues searching there on the next expression after the expression it just finished searching. If there is none, it ascends again, etc. This process continues until the entire edit chain has been searched, at which point the search fails, and an error is generated. If the search fails (or is aborted by control-E), the edit chain is not changed (nor are any CONSes performed).

If the search is successful, i.e., an expression is found that the pattern matches, the edit chain is set to the value it would have had had the user reached that expression via a sequence of integer commands.

If the expression that matched was a list, it will be the final link in the edit chain, i.e., the new current expression. If the expression that matched is not a list, e.g., is an atom, the current expression will be the tail beginning with that atom, unless the atom is a tail, e.g., B in (A.B). In this case, the current expression will be B, but will print as ... . B). In other words, the search effectively does an UP (unless UPFINDFLG = NIL (initially T). See "Form Oriented Editing", page 16.34).

### 16.3.2 Search Commands

All of the commands below set LASTAIL for use by UP, set UNFIND for use by \ (page 16.28), and do not change the edit chain or perform any CONSes if they are unsuccessful or aborted.

#### **F** PATTERN

[Editor Command]

Actually two commands: the F informs the editor that the *next* command is to be interpreted as a pattern. This is the most common and useful form of the find command. If successful, the edit chain always changes, i.e., F *PATTERN* means find the next instance of *PATTERN*.

If (MEMB PATTERN CURRENT-EXPRESSION) is true, F does not proceed with a full recursive search. If the value of the MEMB is NIL, F invokes the search algorithm described on page 16.20.

Note that if the current expression is (PROG NIL LP (COND (-- (GO LP1))) ... LP1 ...), then F LP1 will find the PROG label, not the LP1 inside of the GO expression, even though the latter appears first (in print order) in the current expression. Note that typing 1 (making the atom PROG be the current expression) followed by F LP1 would find the first LP1.

### F PATTERN N

[Editor Command]

Same as F PATTERN, i.e., Finds the Next instance of PATTERN, except that the MEMB check of F PATTERN is not performed.

### F PATTERN T

[Editor Command]

Similar to F PATTERN, except that it may succeed without changing the edit chain, and it does not perform the MEMB check.

For example, if the current expression is (COND ...), F COND will look for the next COND, but (F COND T) will "stay here".

### (F PATTERN N)

[Editor Command]

(N > = 1) Finds the Nth place that PATTERN matches. Equivalent to (F PATTERN T) followed by (F PATTERN N) repeated N-1 times. Each time PATTERN successfully matches, N is decremented by 1, and the search continues, until N reaches 0. Note that PATTERN does not have to match with N identical expressions; it just has to match N times. Thus if the current expression is (FOO1 FOO2 FOO3), (F FOO\$ 3) will find FOO3.

If *PATTERN* does not match successfully *N* times, an error is generated and the edit chain is unchanged (even if *PATTERN* matched *N*-1 times).

### (F PATTERN)

[Editor Command]

### F PATTERN NIL

[Editor Command]

Similar to F PATTERN, except that it only matches with elements at the top level of the current expression, i.e., the search will not descend into the current expression, nor will it go outside of the current expression. May succeed without changing the edit chain.

For example, if the current expression is (PROG NIL (SETQ X (COND & &)) (COND &) ...), the command F COND will find the COND inside the SETQ, whereas (F (COND --)) will find the top level COND, i.e., the second one.

### (FS PATTERN<sub>1</sub> ... PATTERN<sub>N</sub>)

[Editor Command]

Equivalent to F  $PATTERN_1$  followed by F  $PATTERN_2$  ... followed by F  $PATTERN_N$ , so that if F  $PATTERN_M$  fails, the edit chain is left at the place  $PATTERN_{M-1}$  matched.

### (F = EXPRESSION X)

[Editor Command]

Equivalent to (F ( = = . EXPRESSION) X), i.e., searches for a structure EQ to EXPRESSION (see page 16.18).

### (ORF PATTERN<sub>1</sub> ... PATTERN<sub>N</sub>)

[Editor Command]

Equivalent to (F (\*ANY\*PATTERN<sub>1</sub> ... PATTERN<sub>N</sub>) N), i.e., searches for an expression that is matched by either PATTERN<sub>1</sub>,  $PATTERN_2$ , ... or  $PATTERN_N$  (see page 16.18).

### **BF** PATTERN

### [Editor Command]

"Backwards Find". Searches in reverse print order, beginning with the expression immediately before the current expression (unless the current expression is the top level expression, in which case **BF** searches the entire expression, in reverse order).

**BF** uses the same pattern match routine as **F**, and **MAXLEVEL** and **UPFINDFLG** have the same effect, but the searching begins at the end of each list, and descends into each element before attempting to match that element. If unsuccessful, the search continues with the next previous element, etc., until the front of the list is reached, at which point **BF** ascends and backs up, etc.

For example, if the current expression is

(PROG NIL (SETQ X (SETQ Y (LIST Z))) (COND ((SETQ W --) --)) --),

the command F LIST followed by BF SETQ will leave the current expression as (SETQ Y (LIST Z)), as will F COND followed by BF SETQ.

#### **BF PATTERN T**

### [Editor Command]

Similar to **BF** PATTERN, except that the search always includes the current expression, i.e., starts at the end of current expression and works backward, then ascends and backs up, etc.

Thus in the previous example, where F COND followed by BF SETQ found (SETQ Y (LIST Z)), F COND followed by (BF SETQ T) would find the (SETQ W --) expression.

#### (BF PATTERN)

#### [Editor Command]

### **BF PATTERN NIL**

### [Editor Command]

#### Same as BF PATTERN.

#### (GO LABEL)

#### [Editor Command]

Makes the current expression be the first thing after the PROG label LABEL, i.e. goes where an executed GO would go.

## 16.3.3 Location Specification

Many of the more sophisticated commands described later in this chapter use a more general method of specifying position called a "location specification." A location specification is a list of edit commands that are executed in the normal fashion with two exceptions. First, all commands not recognized by the editor are interpreted as though they had been preceded by F; normally such commands would cause errors. For example, the location

specification (COND 2 3) specifies the 3rd element in the first clause of the next COND. Note that the user could always write F COND followed by 2 and 3 for (COND 2 3) if he were not sure whether or not COND was the name of an atomic command.

Secondly, if an error occurs while evaluating one of the commands in the location specification, and the edit chain had been changed, i.e., was not the same as it was at the beginning of that execution of the location specification, the location operation will continue. In other words, the location operation keeps going unless it reaches a state where it detects that it is "looping", at which point it gives up. Thus, if (COND 2 3) is being located, and the first clause of the next COND contained only two elements, the execution of the command 3 would cause an error. The search would then continue by looking for the next COND. However, if a point were reached where there were no further CONDs, then the first command, COND, would cause the error; the edit chain would not have been changed, and so the entire location operation would fail, and cause an error.

The IF command (page 16.60) in conjunction with the ## function (page 16.59) provide a way of using arbitrary predicates applied to elements in the current expression. IF and ## will be described in detail later in the chapter, along with examples illustrating their use in location specifications.

Throughout this chapter, the meta-symbol @ is used to denote a location specification. Thus @ is a list of commands interpreted as described above. @ can also be atomic, in which case it is interpreted as (LIST @).

#### (LC . @)

[Editor Command]

Provides a way of explicitly invoking the location operation, e.g., (LC COND 2 3) will perform the the search described above.

### (LCL . @)

[Editor Command]

Same as LC except the search is confined to the current expression, i.e., the edit chain is rebound during the search so that it looks as though the editor were called on just the current expression. For example, to find a COND containing a RETURN, one might use the location specification (COND (LCL RETURN) \) where the \ would reverse the effects of the LCL command, and make the final current expression be the COND.

## (2ND . @)

[Editor Command]

Same as (LC.@) followed by another (LC.@) except that if the first succeeds and second fails, no change is made to the edit chain.

16.24

COMMANDS THAT SEARCH (3ND . @) [Editor Command] Similar to 2ND. (← PATTERN) [Editor Command] Ascends the edit chain looking for a link which matches PATTERN. In other words, it keeps doing 0's until it gets to a specified point. If PATTERN is atomic, it is matched with the first element of each link, otherwise with the entire link. If no match is found, an error is generated, and the edit chain is unchanged. Note: If PATTERN is of the form (IF EXPRESSION), EXPRESSION is evaluated at each link, and if its value is NIL, or the evaluation causes an error, the ascent continues. See page 16.60. For example: \*PP [PROG NIL (COND [(NULL (SETQ L (CDR L))) (COND (FLG (RETURN L) ([NULL (CDR (FMEMB (CAR L) (CADR L]] \*F CADR \*(← COND) \*P (COND (& &) (& &)) Note that this command differs from BF in that it does not search inside of each link, it simply ascends. Thus in the above example, F CADR followed by BF COND would find (COND (FLG (RETURN L))), not the higher COND. (BELOW COM X) [Editor Command] Ascends the edit chain looking for a link specified by COM, and

stops X links below that (only links that are elements are counted, not tails). In other words BELOW keeps doing 0's until it gets to a specified point, and then backs off X **0**'s.

Note that X is evaluated, so one can type (BELOW COM (IPLUS X Y)).

### (BELOW COM)

[Editor Command]

Same as (BELOW COM 1).

For example, (BELOW COND) will cause the COND clause containing the current expression to become the new current expression. Thus if the current expression is as shown above, F CADR followed by (BELOW COND) will make the new expression be ([NULL (CDR (FMEMB (CAR L) (CADR L] (GO LP)), and is therefore equivalent to 0 0 0 0.

The **BELOW** command is useful for locating a substructure by specifying something it contains. For example, suppose the user is editing a list of lists, and wants to find a sublist that contains a **FOO** (at any depth). He simply executes **FFOO** (**BELOW** \).

### (NEX COM)

[Editor Command]

#### Same as (BELOW COM) followed by NX.

For example, if the user is deep inside of a SELECTQ clause, he can advance to the next clause with (NEX SELECTQ).

#### NEX

[Editor Command]

### Same as (NEX $\leftarrow$ ).

The atomic form of **NEX** is useful if the user will be performing repeated executions of **(NEX** *COM*). By simply **MARK**ing (see page 16.28) the chain corresponding to *COM*, he can use **NEX** to step through the sublists.

#### (NTH COM)

[Editor Command]

Generalized NTH command. Effectively performs (LCL . COM), followed by (BELOW \), followed by UP.

If the search is unsuccessful, **NTH** generates an error and the edit chain is not changed.

Note that (NTH NUMBER) is just a special case of (NTH COM), and in fact, no special check is made for COM a number; both commands are executed identically.

In other words, NTH locates COM, using a search restricted to the current expression, and then backs up to the current level, where the new current expression is the tail whose first element contains, however deeply, the expression that was the terminus of the location operation. For example:

\*p

(PROG (& &) LP (COND & &) (EDITCOM &) (SETQ UNFIND UF) (RETURN L))

\*(NTH UF)

\*P

... (SETQ UNFIND UF) (RETURN L))

Ť

[Editor Command]

E.g., (COND.. RETURN). Finds a COND that contains a RETURN, at any depth. Equivalent to (but more efficient than) (F PATTERN N), (LCL.@) followed by ( $\leftarrow$  PATTERN).

An infix command, ".." is not a meta-symbol, it is the name of the command. @ is CDDR of the command. Note that (PATTERN .. @) can also be used directly as an edit pattern as described on page 16.18, e.g. F (PATTERN .. @).

For example, if the current expression is

(PROG NIL [COND ((NULL L) (COND (FLG (RETURN L] --),

then (COND .. RETURN) will make (COND (FLG (RETURN L))) be the current expression. Note that it is the innermost COND that is found, because this is the first COND encountered when ascending from the RETURN. In other words, (PATTERN .. @) is not always equivalent to (F PATTERN N), followed by (LCL . @) followed by \.

Note that @ is a location specification, not just a pattern. Thus (RETURN .. COND 2 3) can be used to find the RETURN which contains a COND whose first clause contains (at least) three elements. Note also that since @ permits any edit command, the user can write commands of the form (COND .. (RETURN .. COND)), which will locate the first COND that contains a RETURN that contains a COND.

## 16.4 Commands That Save and Restore the Edit Chain

Several facilities are available for saving the current edit chain and later retrieving it: MARK, which marks the current chain for future reference,  $\leftarrow$ , which returns to the last mark without destroying it, and  $\leftarrow\leftarrow$ , which returns to the last mark and also erases it.

MARK

[Editor Command]

Adds the current edit chain to the front of the list MARKLST.

[Editor Command]

Makes the new edit chain be (CAR MARKLST). Generates an error if MARKLST is NIL, i.e., no MARKs have been performed, or all have been erased.

This is an atomic command; do not confuse it with the list command ( $\leftarrow PATTERN$ ).

	[Editor Command]
	Similar to ← but also erases the last MARK, i.e., performs (SETQ MARKLST (CDR MARKLST)).
	Note that if the user has two chains marked, and wishes to return to the first chain, he must perform ←←, which removes the second mark, and then ←. However, the second mark is then no longer accessible. If the user wants to be able to return to either of two (or more) chains, he can use the following generalized MARK:
(MARK LITATOM)	[Editor Command]
	Sets LITATOM to the current edit chain,
(\LITATOM)	[Editor Command]  Makes the current edit chain become the value of LITATOM.
	iviakes the current edit chain become the value of LITATOW.
	If the user did not prepare in advance for returning to a particular edit chain, he may still be able to return to that chain with a single command by using \ or \P.
\	[Editor Command]
	Makes the edit chain be the value of UNFIND. Generates an error if UNFIND = NIL.
	<b>UNFIND</b> is set to the current edit chain by each command that makes a "big jump", i.e., a command that usually performs more than a single ascent or descent, namely ↑, ←, ←←, !NX, all commands that involve a search, e.g., F, LC,, BELOW, et al and \ and \P themselves. One exception is that UNFIND is not reset when the current edit chain is the top level expression, since this could always be returned to via the ↑ command.
	For example, if the user types F COND, and then F CAR, \ would take him back to the COND. Another \ would take him back to the CAR, etc.
<b>/P</b>	[Editor Command]
	Restores the edit chain to its state as of the last print operation, i.e., P, ?, or PP. If the edit chain has not changed since the last printing, \P restores it to its state as of the printing before that one, i.e., two chains are always saved.
	For example, if the user types P followed by 3 2 1 P, \P will return to the first P, i.e., would be equivalent to 0 0 0. Another \P would then take him back to the second P, i.e., the user could use \P to flip back and forth between the two edit chains.

Note that if the user had typed P followed by F COND, he could use either \ or \P to return to the P, i.e., the action of \ and \P are independent.

#### S LITATOM @

[Editor Command]

Sets *LITATOM* (using **SETQ**) to the current expression after performing (**LC**. @). The edit chain is not changed.

Thus (S FOO) will set FOO to the current expression, and (S FOO -1 1) will set FOO to the first element in the last element of the current expression.

# 16.5 Commands That Modify Structure

The basic structure modification commands in the editor are:

(N)(N>=1)

[Editor Command]

Deletes the corresponding element from the current expression.

 $(N\,E_1\,\ldots\,E_M)\,(N>=1)$ 

[Editor Command]

Replaces the Nth element in the current expression with  $E_1$  ...  $E_M$ .

 $(-NE_1 ... E_M) (N > = 1)$ 

[Editor Command]

Inserts  $E_1$  ...  $E_M$  before the Nth element in the current expression.

 $(N E_1 ... E_M)$ 

[Editor Command]

Attaches  $E_1 \dots E_M$  at the end of the current expression.

As mentioned earlier: all structure modification done by the editor is destructive, i.e., the editor uses RPLACA and RPLACD to physically change the structure it was given. However, all structure modification is undoable, see UNDO (page 16.64).

All of the above commands generate errors if the current expression is not a list, or in the case of the first three commands, if the list contains fewer than N elements. In addition, the command (1), i.e., delete the first element, will cause an error if there is only one element, since deleting the first element must be done by replacing it with the second element, and then deleting the second element. Or, to look at it another way, deleting the first element when there is only one element would

require changing a list to an atom (i.e., to **NIL**) which cannot be done. However, the command **DELETE** will work even if there is only one element in the current expression, since it will ascend to a point where it *can* do the deletion.

If the value of CHANGESARRAY is a hash array, the editor will mark all structures that are changed by doing (PUTHASH STRUCTURE FN CHANGESARRAY), where FN is the name of the function. The algorithm used for marking is as follows: (1) If the expression is inside of another expression already marked as being changed, do nothing. (2) If the change is an insertion of or replacement with a list, mark the list as changed. (3) If the change is an insertion of or replacement with an atom, or a deletion, mark the parent as changed.

CHANGESARRAY is primarily for use by PRETTYPRINT (page 26.40). When the value of CHANGECHAR is non-NIL, PRETTYPRINT, when printing to a file or display terminal, prints CHANGECHAR in the right margin while printing an expression marked as having been changed. CHANGECHAR is initially |.

## 16.5.1 Implementation

Note: Since all commands that insert, replace, delete or attach structure use the same low level editor functions, the remarks made here are valid for all structure changing commands.

For all replacement, insertion, and attaching at the end of a list, unless the command was typed in directly to the editor, copies of the corresponding structure are used, because of the possibility that the exact same command, (i.e., same list structure) might be used again. Thus if a program constructs the command (1 (A B C)) e.g., via (LIST 1 FOO), and gives this command to the editor, the (A B C) used for the replacement will not be EQ to FOO. The user can circumvent this by using the I command (page 16.58), which computes the structure to be used. In the above example, the form of the command would be (I 1 FOO), which would replace the first element with the value of FOO itself.

Note: Some editor commands take as arguments a list of edit commands, e.g., (LP F FOO (1 (CAR FOO))). In this case, the command (1 (CAR FOO)) is not considered to have been "typed in" even though the LP command itself may have been typed in. Similarly, commands originating from macros, or commands given to the editor as arguments to EDITF, EDITV, et al, e.g., EDITF(FOO F COND (N --)) are not considered typed in.

The rest of this section is included for applications wherein the editor is used to modify a data structure, and pointers into that data structure are stored elsewhere. In these cases, the actual mechanics of structure modification must be known in order to predict the effect that various commands may have on these

outside pointers. For example, if the value of FOO is CDR of the current expression, what will the commands (2), (3), (2 X Y Z), (-2 X Y Z), etc. do to FOO?

Deletion of the first element in the current expression is performed by replacing it with the second element and deleting the second element by patching around it. Deletion of any other element is done by patching around it, i.e., the previous tail is altered. Thus if FOO is EQ to the current expression which is (A B C D), and FIE is CDR of FOO, after executing the command (1), FOO will be (B C D) (which is EQUAL but not EQ to FIE). However, under the same initial conditions, after executing (2) FIE will be unchanged, i.e., FIE will still be (B C D) even though the current expression and FOO are now (A C D).

A general solution of the problem isn't possible, as it would require being able to make two lists EQ to each other that were originally different. Thus if FIE is CDR of the current expression, and FUM is CDDR of the current expression, performing (2) would have to make FIE be EQ to FUM if all subsequent operations were to update both FIE and FUM correctly.

Both replacement and insertion are accomplished by smashing both CAR and CDR of the corresponding tail. Thus, if FOO were EQ to the current expression, (A B C D), after (1 X Y Z), FOO would be (X Y Z B C D). Similarly, if FOO were EQ to the current expression, (A B C D), then after (-1 X Y Z), FOO would be (X Y Z A B C D).

The N command is accomplished by smashing the last CDR of the current expression a la NCONC. Thus if FOO were EQ to any tail of the current expression, after executing an N command, the corresponding expressions would also appear at the end of FOO.

In summary, the only situation in which an edit operation will not change an external pointer occurs when the external pointer is to a proper tail of the data structure, i.e., to CDR of some node in the structure, and the operation is deletion. If all external pointers are to elements of the structure, i.e., to CAR of some node, or if only insertions, replacements, or attachments are performed, the edit operation will always have the same effect on an external pointer as it does on the current expression.

## 16.5.2 The A, B, and: Commands

In the (N), (N  $E_1$  ...  $E_M$ ), and (-N  $E_1$  ...  $E_M$ ) commands, the sign of the integer is used to indicate the operation. As a result, there is no direct way to express insertion after a particular element, (hence the necessity for a separate N command). Similarly, the user cannot specify deletion or replacement of the Nth element

	corresponding positive integer. Accordingly, we have:
(B E <sub>1</sub> E <sub>M</sub> )	[Editor Command]
	Inserts $E_1 \dots E_M$ before the current expression. Equivalent to UP followed by (-1 $E_1 \dots E_M$ ).
	For example, to insert FOO before the last element in the current expression, perform -1 and then (B FOO).
(A E <sub>1</sub> E <sub>M</sub> )	[Editor Command]
	Inserts $E_1$ $E_M$ after the current expression. Equivalent to UP followed by (-2 $E_1$ $E_M$ ) or (N $E_1$ $E_M$ ), whichever is appropriate.
(: E <sub>1</sub> E <sub>M</sub> )	[Editor Command]
	Replaces the current expression by $E_1 \dots E_M$ . Equivalent to <b>UP</b> followed by (1 $E_1 \dots E_M$ ).
DELETE	[Editor Command]
(:)	[Editor Command]
	Deletes the current expression.
	DELETE first tries to delete the current expression by performing an UP and then a (1). This works in most cases. However, if after performing UP, the new current expression contains only one element, the command (1) will not work. Therefore, DELETE starts over and performs a BK, followed by UP, followed by (2). For example, if the current expression is (COND ((MEMB X Y))) (TY)), and the user performs -1, and then DELETE, the BK-UP-(2) method is used, and the new current expression will be ((MEMB X Y))).
	However, if the next higher expression contains only one element, BK will not work. So in this case, DELETE performs UP, followed by (: NIL), i.e., it replaces the higher expression by NIL.

followed by (: NIL), i.e., it replaces the higher expression by NIL. For example, if the current expression is (COND ((MEMB X Y)) (T Y)) and the user performs F MEMB and then DELETE, the new current expression will be ... NIL (T Y)) and the original expression would now be (COND NIL (T Y)). The rationale behind this is that deleting (MEMB X Y) from ((MEMB X Y)) changes a list of one element to a list of no elements, i.e., () or NIL.

from the end of a list without first converting N to the

If the current expression is a tail, then **B**, **A**, :, and **DELETE** all work exactly the same as though the current expression were the first element in that tail. Thus if the current expression were ...

(PRINT Y) (PRINT Z)), (B (PRINT X)) would insert (PRINT X) before (PRINT Y), leaving the current expression ... (PRINT X) (PRINT Y) (PRINT Z)).

The following forms of the A, B, and : commands incorporate a location specification:

## (INSERT E1 ... EM BEFORE. @)

[Editor Command]

(@ is (CDR (MEMBER 'BEFORE COMMAND))) Similar to (LC .@) followed by (B  $E_1 \dots E_M$ ).

Warning: If @ causes an error, the location process does *not* continue as described on page 16.23. For example if @ = (COND 3) and the next COND does not have a 3rd element, the search stops and the INSERT fails. Note that the user can always write (LC COND 3) if he intends the search to continue.

\*D

(PROG (& & X) \*\*COMMENT\*\* (SELECTQ ATM & NIL) (OR & &)
(PRIN1 & T)
(PRIN1 & T) (SETQ X &

\*(INSERT LABEL BEFORE PRIN1)

\*P

(PROG (& & X) \*\*COMMENT\*\* (SELECTQ ATM & NIL) (OR & &)
LABEL

(PRIN1 & T) ( user typed control-E

,

Current edit chain is not changed, but **UNFIND** is set to the edit chain after the **B** was performed, i.e., \ will make the edit chain be that chain where the insertion was performed.

## (INSERT $E_1 \dots E_M$ AFTER . @)

[Editor Command]

Similar to INSERT BEFORE except uses A instead of B.

(INSERT  $E_1 \dots E_M$  FOR . @)

[Editor Command]

Similar to INSERT BEFORE except uses: for B.

(REPLACE @ BY  $E_1 \dots E_M$ )

[Editor Command]

(REPLACE @ WITH  $E_1 \dots E_M$ )

[Editor Command]

Here @ is the segment of the command between REPLACE and WITH. Same as (INSERT  $E_1 \dots E_M$  FOR . @).

Example: (REPLACE COND -1 WITH (T (RETURN L)))

(CHANGE @ TO  $E_1 \dots E_M$ )

[Editor Command]

#### Same as REPLACE WITH.

### (DELETE . @)

[Editor Command]

Does a (LC.@) followed by DELETE (see warning about INSERT, page 16.33). The current edit chain is not changed, but UNFIND is set to the edit chain after the DELETE was performed.

Note: the edit chain will be changed if the current expression is no longer a part of the expression being edited, e.g., if the current expression is ... C) and the user performs (DELETE 1), the tail, (C), will have been cut off. Similarly, if the current expression is (CDR Y) and the user performs (REPLACE WITH (CAR X)).

Example: (DELETE -1), (DELETE COND 3)

Note: if @ is NIL (i.e., empty), the corresponding operation is performed on the current edit chain.

For example, (REPLACE WITH (CAR X)) is equivalent to (: (CAR X)). For added readability, HERE is also permitted, e.g., (INSERT (PRINT X) BEFORE HERE) will insert (PRINT X) before the current expression (but not change the edit chain).

Note: @ does not have to specify a location within the current expression, i.e., it is perfectly legal to ascend to INSERT, REPLACE, or DELETE

For example, (INSERT (RETURN) AFTER ↑ PROG -1) will go to the top, find the first PROG, and insert a (RETURN) at its end, and not change the current edit chain.

The A, B, and : commands, commands, (and consequently INSERT, REPLACE, and CHANGE), all make special checks in  $E_1$  thru  $E_M$  for expressions of the form (## . COMS). In this case, the expression used for inserting or replacing is a copy of the current expression after executing COMS, a list of edit commands (the execution of COMS does not change the current edit chain). For example, (INSERT (## F COND -1 -1) AFTER 3) will make a copy of the last form in the last clause of the next COND, and insert it after the third element of the current expression. Note that this is not the same as (INSERT F COND -1 (## -1) AFTER 3), which inserts four elements after the third element, namely F, COND, -1, and a copy of the last element in the current expression.

# 16.5.3 Form Oriented Editing and the Role of UP

The **UP** that is performed before **A**, **B**, and : commands (and therefore in **INSERT**, **CHANGE**, **REPLACE**, and **DELETE** commands after the location portion of the operation has been performed)

makes these operations form-oriented. For example, if the user types F SETQ, and then DELETE, or simply (DELETE SETQ), he will delete the entire SETQ expression, whereas (DELETE X) if X is a variable, deletes just the variable X. In both cases, the operation is performed on the corresponding form, and in both cases is probably what the user intended. Similarly, if the user types (INSERT (RETURN Y) BEFORE SETQ), he means before the SETQ expression, not before the atom SETQ. A consequent of this procedure is that a pattern of the form (SETQ Y --) can be viewed as simply an elaboration and further refinement of the pattern SETQ. Thus (INSERT (RETURN Y) BEFORE SETQ) and (INSERT (RETURN Y) BEFORE (SETQ Y --)) perform the same operation (assuming the next SETQ is of the form (SETQ Y --)) and, in fact, this is one of the motivations behind making the current expression after F SETQ, and F (SETQ Y --) be the same.

Note: There is some ambiguity in (INSERT EXPR AFTER FUNCTIONNAME), as the user might mean make EXPR be the function's first argument. Similarly, the user cannot write (REPLACE SETQ WITH SETQQ) meaning change the name of the function. The user must in these cases write (INSERT EXPR AFTER FUNCTIONNAME 1), and (REPLACE SETQ 1 WITH SETQQ).

Occasionally, however, a user may have a data structure in which no special significance or meaning is attached to the position of an atom in a list, as Interlisp attaches to atoms that appear as CAR of a list, versus those appearing elsewhere in a list. In general, the user may not even know whether a particular atom is at the head of a list or not. Thus, when he writes (INSERT EXPR BEFORE FOO), he means before the atom FOO, whether or not it is CAR of a list. By setting the variable UPFINDFLG to NIL (initially T), the user can suppress the implicit UP that follows searches for atoms, and thus achieve the desired effect. With UPFINDFLG = NIL, following F FOO, for example, the current expression will be the atom FOO. In this case, the A, B, and: operations will operate with respect to the atom FOO. If the user intends the operation to refer to the list which FOO heads, he simply uses instead the pattern (FOO --).

### 16.5.4 Extract and Embed

Extraction involves replacing the current expression with one of its subexpressions (from any depth).

(XTR.@)

[Editor Command]

Replaces the original current expression with the expression that is current after performing (LCL.@) (see warning about INSERT, page 16.33). If the current expression after (LCL.@) is a *tail* of a higher expression, its first element is used.

If the extracted expression is a list, then after XTR has finished, the current expression will be that list. If the extracted expression is not a list, the new current expression will be a tail whose first element is that non-list.

For example, if the current expression is (COND ((NULL X) (PRINT Y))), (XTR PRINT), or (XTR 2 2) will replace the COND by the PRINT. The current expression after the XTR would be (PRINT Y).

If the current expression is (COND ((NULL X) Y) (T Z)), then (XTR Y) will replace the COND with Y, even though the current expression after performing (LCL Y) is ... Y). The current expression after the XTR would be ... Y followed by whatever followed the COND.

If the current expression initially is a tail, extraction works exactly the same as though the current expression were the first element in that tail. Thus if the current expression is ... (COND ((NULL X) (PRINT Y))) (RETURN Z)), then (XTR PRINT) will replace the COND by the PRINT, leaving (PRINT Y) as the current expression.

The extract command can also incorporate a location specification:

## (EXTRACT @<sub>1</sub> FROM . @<sub>2</sub>)

[Editor Command]

Performs (LC . @<sub>2</sub>) and then (XTR . @<sub>1</sub>) (see warning about INSERT, page 16.33). The current edit chain is not changed, but UNFIND is set to the edit chain after the XTR was performed.

Note: @1 is the segment between EXTRACT and FROM.

For example: If the current expression is (PRINT (COND ((NULL X) Y) (T Z))) then following (EXTRACT Y FROM COND), the current expression will be (PRINT Y). (EXTRACT 2 -1 FROM COND), (EXTRACT Y FROM 2), and (EXTRACT 2 -1 FROM 2) will all produce the same result.

While extracting replaces the current expression by a subexpression, embedding replaces the current expression with one containing it as a subexpression.

## (MBD $E_1 \dots E_M$ )

[Editor Command]

**MBD** substitutes the current expression for all instances of the atom & in  $E_1 \dots E_M$ , and replaces the current  $\curvearrowright$  or ession with the result of that substitution. As with SUBST, a fresh copy is used for each substitution.

If & does not appear in  $E_1 \dots E_M$ , the MBD is interpreted as (MBD  $(E_1 \dots E_M \&)$ ).

MBD leaves the edit chain so that the larger expression is the new current expression.

### Examples:

If the current expression is (PRINT Y), (MBD (COND ((NULL X) &) ((NULL (CAR Y)) & (GO LP)))) would replace (PRINT Y) with (COND ((NULL X) (PRINT Y)) ((NULL (CAR Y)) (PRINT Y) (GO LP))).

If the current expression is (RETURN X), (MBD (PRINT Y) (AND FLG &)) would replace it with the two expressions (PRINT Y) and (AND FLG (RETURN X)) i.e., if the (RETURN X) appeared in the cond clause (T (RETURN X)), after the MBD, the clause would be (T (PRINT Y) (AND FLG (RETURN X))).

If the current expression is (PRINT Y), then (MBD SETQ X) will replace it with (SETQ X (PRINT Y)). If the current expression is (PRINT Y), (MBD RETURN) will replace it with (RETURN (PRINT Y)).

If the current expression *initially* is a tail, embedding works exactly the same as though the current expression were the first element in that tail. Thus if the current expression were ... (PRINT Y) (PRINT Z)), (MBD SETQ X) would replace (PRINT Y) with (SETQ X (PRINT Y)).

The embed command can also incorporate a location specification:

### (EMBED @ IN . X)

[Editor Command]

(@ is the segment between EMBED and IN.) Does (LC. @) and then (MBD. X) (see warning about INSERT, page 16.33). Edit chain is not changed, but UNFIND is set to the edit chain after the MBD was performed.

Examples: (EMBED PRINT IN SETQ X), (EMBED 3 2 IN RETURN), (EMBED COND 3 1 IN (OR & (NULL X))).

WITH can be used for IN, and SURROUND can be used for EMBED, e.g., (SURROUND NUMBERP WITH (AND & (MINUSP X))).

#### **EDITEMBEDTOKEN**

[Variable]

The special atom used in the MBD and EMBED commands is the value of this variable, initially &.

### 16.5.5 The MOVE Command

The MOVE command allows the user to specify (1) the expression to be moved, (2) the place it is to be moved to, and (3) the operation to be performed there, e.g., insert it before, insert it after, replace, etc.

\*7

\*?

\*P

\*P

\*P

\*P

\*P

(@1 is the segment between MOVE and TO.) COM is BEFORE, AFTER, or the name of a list command, e.g., :, N, etc. Performs (LC.@<sub>1</sub>) (see warning about INSERT, page 16.33), and obtains the current expression there (or its first element, if it is a tail), which we will call EXPR; MOVE then goes back to the original edit chain, performs (LC . @2) followed by (COM EXPR) (setting an internal flag so EXPR is not copied), then goes back to @1 and deletes EXPR. The edit chain is not changed. UNFIND is set to the edit chain after (COM EXPR) was performed.

If @2 specifies a location inside of the expression to be moved, a message is printed and an error is generated, e.g., (MOVE 2 TO AFTER X), where X is contained inside of the second element.

For example, if the current expression is (A B C D), (MOVE 2 TO AFTER 4) will make the new current expression be (A C D B). Note that 4 was executed as of the original edit chain, and that the second element had not yet been removed.

As the following examples taken from actual editing will show, the MOVE command is an extremely versatile and powerful feature of the editor.

```
(PROG ((L L)) (EDLOC (CDDR C)) (RETURN (CAR L)))
*(MOVE 3 TO : CAR)
(PROG ((L L)) (RETURN (EDLOC (CDDR C))))
... (SELECTQ OBJPR & &) (RETURN &) LP2 (COND & &))
*(MOVE 2 TO N 1)
... (SELECTQ OBJPR & & &) LP2 (COND & &))
(OR (EQ X LASTAIL) (NOT &) (AND & & &))
*(MOVE 4 TO AFTER (BELOW COND))
(OR (EQ X LASTAIL) (NOT &))
*\ P
... (& &) (AND & & &) (T & &))
((NULL X) **COMMENT** (COND & &))
*(-3 (GO NXT)
```

```
*(MOVE 4 TO N (\leftarrow PROG))
((NULL X) **COMMENT** (GO NXT))
*\ P
(PROG (&) **COMMENT** (COND & & &) (COND & & &) (COND &
*(INSERT NXT BEFORE -1)
*P
(PROG (&) **COMMENT** (COND & & &) (COND & & &) NXT
(COND & &))
Note that in the last example, the user could have added the
PROG label NXT and moved the COND in one operation by
performing (MOVE 4 TO N (← PROG) (N NXT)). Similarly, in the
next example, in the course of specifying @2, the location where
the expression was to be moved to, the user also performs a
structure modification, via (N (T)), thus creating the structure
that will receive the expression being moved.
*P
((CDR &) **COMMENT** (SETQ CL &) (EDITSMASH CL & &))
*MOVE 4 TO N 0 (N (T)) -1]
*P
((CDR &) **COMMENT** (SETQ CL &))
*(T (EDITSMASH CL & &))
If @2 is NIL, or (HERE), the current position specifies where the
operation is to take place. In this case, UNFIND is set to where
the expression that was moved was originally located, i.e., @1.
For example:
*P
(TENEX)
*(MOVE ↑ FAPPLY TO N HERE)
(TENEX (APPLY & &))
(PROG (& & & ATM IND VAL) (OR & &) **COMMENT** (OR & &)
(PRIN1 & T) (
PRIN1 & T) (SETQ IND
                      user typed control-E
*(MOVE * TO BEFORE HERE)
(PROG (& & & ATM IND VAL) (OR & &) (OR & &) (PRIN1 &
(T (PRIN1 C-EXP T))
```

```
*(MOVE ↑ BF PRIN1 TO N HERE)
*P
(T (PRIN1 C-EXP T) (PRIN1 & T))
```

Finally, if @<sub>1</sub> is NIL, the MOVE command allows the user to specify where the *current expression* is to be moved to. In this case, the edit chain is changed, and is the chain where the current expression was moved to; UNFIND is set to where it was.

```
*P
(SELECTQ OBJPR (&) (PROGN & &))
*(MOVE TO BEFORE LOOP)
*P
... (SELECTQ OBJPR & &) LOOP (FRPLACA DFPRP &) (FRPLACD DFPRP
&) (SELECTQ user typed control-E
```

## 16.5.6 Commands That Move Parentheses

The commands presented in this section permit modification of the list structure itself, as opposed to modifying components thereof. Their effect can be described as inserting or removing a single left or right parenthesis, or pair of left and right parentheses. Of course, there will always be the same number of left parentheses as right parentheses in any list structure, since the parentheses are just a notational guide to the structure provided by PRINT. Thus, no command can insert or remove just one parenthesis, but this is suggestive of what actually happens.

In all six commands, N and M are used to specify an element of a list, usually of the current expression. In practice, N and M are usually positive or negative integers with the obvious interpretation. However, all six commands use the generalized NTH command (NTH COM) to find their element(s), so that Nth element means the first element of the tail found by performing (NTH N). In other words, if the current expression is (LIST (CAR X) (SETQ Y (CONS W Z))), then (BI 2 CONS), (BI X -1), and (BI X Z) all specify the exact same operation.

All six commands generate an error if the element is not found, i.e., the NTH fails. All are undoable.

(BINM)

[Editor Command]

"Both In". Inserts a left parentheses before the Nth element and after the Mth element in the current expression. Generates an error if the Mth element is not contained in the Nth tail, i.e., the Mth element must be "to the right" of the Nth element.

	Example: If the current expression is (A B (C D E) F G), then (BI 2 4) will modify it to be (A (B (C D E) F) G).
(BI N)	[Editor Command]
	Same as (BI N N).
	Example: If the current expression is (A B (C D E) F G), then (BI -2) will modify it to be (A B (C D E) (F) G).
(BO N)	[Editor Command]
	"Both Out". Removes both parentheses from the Nth element. Generates an error if Nth element is not a list.
	Example: If the current expression is (A B (C D E) F G), then (BO D) will modify it to be (A B C D E F G).
(LI N)	[Editor Command]
	"Left In". Inserts a left parenthesis before the Nth element (and a matching right parenthesis at the end of the current expression), i.e. equivalent to (BI N -1).
	Example: if the current expression is (A B (C D E) F G), then (LI 2) will modify it to be (A (B (C D E) F G)).
(LO N)	[Editor Command]
(1014)	"Left Out". Removes a left parenthesis from the Nth element.  All elements following the Nth element are deleted. Generates an error if Nth element is not a list.
	Example: If the current expression is (A B (C D E) F G), then (LO 3) will modify it to be (A B C D E).
(RI <i>N M</i> )	[Editor Command]
· · · · · · · · · · · · · · · · · · ·	"Right In". Inserts a right parenthesis after the Mth element of the Nth element. The rest of the Nth element is brought up to the level of the current expression.
	Example: If the current expression is (A (B C D E) F G), (RI 2 2) will modify it to be (A (B C) D E F G). Another way of thinking about RI is to read it as "move the right parenthesis at the end of the Nth element in to after its Nth element."
(RO N)	[Editor Command]
**************************************	"Right Out". Removes the right parenthesis from the <i>N</i> th element, moving it to the end of the current expression. All

elements following the Nth element are moved inside of the Nth element. Generates an error if Nth element is not a list.

Example: If the current expression is (A B (C D E) F G), (RO 3) will modify it to be (A B (C D E F G)). Another way of thinking about RO is to read it as "move the right parenthesis at the end of the Nth element out to the end of the current expression."

## 16.5.7 TO and THRU

**EXTRACT, EMBED, DELETE, REPLACE,** and **MOVE** can be made to operate on several contiguous elements, i.e., a segment of a list, by using in their respective location specifications the **TO** or **THRU** command.

# (@1 THRU @2)

[Editor Command]

Does a (LC. @<sub>1</sub>), followed by an UP, and then a (BI 1 @<sub>2</sub>), thereby grouping the segment into a single element, and finally does a 1, making the final current expression be that element.

For example, if the current expression is (A (B (C D) (E) (F G H) I) J K), following (C THRU G), the current expression will be ((C D) (E) (F G H)).

# (@<sub>1</sub> TO @<sub>2</sub>)

[Editor Command]

Same as THRU except the last element not included, i.e., after the BI, an (RI 1 -2) is performed.

If both  $@_1$  and  $@_2$  are numbers, and  $@_2$  is greater than  $@_1$ , then  $@_2$  counts from the beginning of the current expression, the same as  $@_1$ . In other words, if the current expression is (A B C D E F G), (3 THRU 5) means (C THRU E) not (C THRU G). In this case, the corresponding BI command is (BI 1  $@_2$ - $@_1$  + 1).

THRU and TO are not very useful commands by themselves; they are intended to be used in conjunction with EXTRACT, EMBED, DELETE, REPLACE, and MOVE. After THRU and TO have operated, they set an internal editor flag informing the above commands that the element they are operating on is actually a segment, and that the extra pair of parentheses should be removed when the operation is complete. Thus:

\*P

(PROG (& & ATM IND VAL WORD) (PRIN1 & T) (PRIN1 & T) (SETQ IND &)
(SETQ VAL &) \*\*COMMENT\*\* (SETQQ user typed control-E

```
*(MOVE (3 THRU 4) TO BEFORE 7)
*P
(PROG (& & ATM IND VAL WORD) (SETQ IND &) (SETQ VAL &)
(PRIN1 & T)
(PRIN1 & T) **COMMENT** user typed control-E
*P
(* FAIL RETURN FROM EDITOR. USER SHOULD NOTE THE VALUES
OF SOURCEXPR
AND CURRENTFORM. CURRENTFORM IS THE LAST FORM IN
SOURCEXPR WHICH WILL
HAVE BEEN TRANSLATED, AND IT CAUSED THE ERROR.)
*(DELETE (USER THRU CURR$))
= CURRENTFORM.
*P
(* FAIL RETURN FROM EDITOR. CURRENTFORM IS user typed
control-E
*P
... LP (SELECTO & & & & NIL) (SETQ Y &) OUT (SETQ FLG &)
(RETURN Y))
*(MOVE (1 TO OUT) TO N HERE]
... OUT (SETQ FLG &) (RETURN Y) LP (SELECTQ & & & & NIL) (SETQ
Y &))
*PP
[PROG (RF TEMP1 TEMP2)
 (COND
  ((NOT (MEMB REMARG LISTING))
   (SETQ TEMP1 (ASSOC REMARG NAMEDREMARKS))
**COMMENT**
   (SETQ TEMP2 (CADR TEMP1))
   (GO SKIP))
  (T **COMMENT**
   (SETQ TEMP1 REMARG)))
 (NCONC1 LISTING REMARG)
 (COND
  ((NOT (SETQ TEMP2 (SASSOC
*(EXTRACT (SETQ THRU CADR) FROM COND)
(PROG (RF TEMP1 TEMP2) (SETQ TEMP1 &) **COMMENT**
(SETQ TEMP2 &) (NCONC1 LISTING REMARG) (COND & & user
typed control-E
```

\*

TO and THRU can also be used directly with XTR, because XTR involves a location specification while A, B, :, and MBD do not. Thus in the previous example, if the current expression had been the COND, e.g., the user had first performed F COND, he could have used (XTR (SETQ THRU CADR)) to perform the extraction.

(@<sub>1</sub> TO)

[Editor Command]

(@1 THRU)

[Editor Command]

Both are the same as (@<sub>1</sub> THRU -1), i.e., from @<sub>1</sub> through the end of the list.

```
Examples:
```

```
*P
(VALUE (RPLACA DEPRP &) (RPLACD &) (RPLACA VARSWORD &)
(RETURN))
*(MOVE (2 TO) TO N (\leftarrow PROG))
*(N (GO VAR))
*P
(VALUE (GO VAR))
(T **COMMENT** (COND &) **COMMENT** (EDITSMASH CL &
&) (COND &))
*(-3 (GO REPLACE))
*(MOVE (COND TO) TO N ↑ PROG (N REPLACE))
*P
(T **COMMENT** (GO REPLACE))
(PROG (&) **COMMENT** (COND & & &) (COND & & &) DELETE
(COND & &) REPLACE
(COND &) **COMMENT** (EDITSMASH CL & &) (COND &))
[LAMBDA (CLAUSALA X)
 (PROG (A D)
  (SETQ A CLAUSALA)
 LP (COND
   ((NULL A)
     (RETURN)))
  (SERCH X A)
  (RUMARK (CDR A))
  (NOTICECL (CAR A))
  (SETQ A (CDR A))
  (GO LP]
```

```
*(EXTRACT (SERCH THRU NOT$) FROM PROG)

= NOTICECL

*P
(LAMBDA (CLAUSALA X) (SERCH X A) (RUMARK &) (NOTICECL

&))

*(EMBED (SERCH TO) IN (MAP CLAUSALA (FUNCTION (LAMBDA
(A) *]

*PP
[LAMBDA (CLAUSALA X)

(MAP CLAUSALA

(FUNCTION (LAMBDA (A)

(SERCH X A)

(RUMARK (CDR A))

(NOTICECL (CAR A]
```

# 16.5.8 The R Command

(RXY)

[Editor Command]

Replaces all instances of X by Y in the current expression, e.g., (R CAADR CADAR). Generates an error if there is not at least one instance.

The **R** command operates in conjunction with the search mechanism of the editor. The search proceeds as described on page 16.20, and X can employ any of the patterns on page 16.18. Each time X matches an element of the structure, the element is replaced by (a copy of) Y; each time X matches a tail of the structure, the tail is replaced by (a copy of) Y.

For example, if the current expression is (A (B C) (B . C)),

(R C D) will change it to (A (B D) (B . D)),

(R (... . C) D) will change it to (A (B C) (B . D)),

(R C (D E)) will change it to (A (B (D E)) (B D E)), and

(R (... . NIL) D) will change it to (A (B C . D) (B . C) . D).

If X is an atom or string containing \$s (escapes), \$s appearing in Y stand for the characters matched by the corresponding \$ in X. For example, (R FOO\$ FIE\$) means for all atoms or strings that begin with FOO, replace the characters "FOO" by "FIE". Applied to the list (FOO FOO2 XFOO1), (R FOO\$ FIE\$) would produce (FIE FIE2 XFOO1), and (R \$FOO\$ \$FIE\$) would produce (FIE FIE2 XFIE1). Similarly, (R \$D\$ \$A\$) will change (LIST (CADR X) (CADDR Y)) to (LIST (CAAR X) (CAADR)). Note that CADDR was not changed to CAAAR, i.e., (R \$D\$ \$A\$) does not mean replace every D with A, but replace the first D in every atom or string by

A. If the user wanted to replace every D by A, he could perform (LP (R \$D\$ \$A\$)).

The user will be informed of all such \$ replacements by a message of the form X->Y, e.g., CADR->CAAR.

If X matches a string, it will be replaced by a string. Note that it does not matter whether X or Y themselves are strings, i.e. (R \$D\$ \$A\$), (R "\$D\$" \$A\$), (R \$D\$ "\$A\$"), and (R "\$D\$" "\$A\$") are equivalent. Note also that X will never match with a number, i.e., (R \$1 \$2) will not change 11 to 12.

Note that the \$ (escape) feature can be used to delete or add characters, as well as replace them. For example, (R \$1 \$) will delete the terminating 1's from all literal atoms and strings. Similarly, if an \$ in X does not have a mate in Y, the characters matched by the \$ are effectively deleted. For example, (R \$/\$ \$) will change AND/OR to AND. There is no similar operation for changing AND/OR to OR, since the first \$ in Y always corresponds to the first \$ in X, the second \$ in Y to the second in X, etc. Y can also be a list containing \$\$, e.g., (R \$1 (CAR \$)) will change FOO1 to (CAR FOO), FIE1 to (CAR FIE).

If X does not contain \$s, \$ appearing in Y refers to the entire expression matched by X, e.g., (R LONGATOM '\$) changes LONGATOM to 'LONGATOM, (R (SETQ X &) (PRINT \$)) changes every (SETQ X &) to (PRINT (SETQ X &)). If X is a pattern containing an \$ pattern somewhere within it, the characters matched by the \$s are not available, and for the purposes of replacement, the effect is the same as though X did not contain any \$s. For example, if the user types (R (CAR F\$) (PRINT \$)), the second \$ will refer to the entire expression matched by (CAR F\$).

Since (R \$X\$ \$Y\$) is a frequently used operation for Replacing Characters, the following command is provided:

(RC X Y)	[Editor Command]
	Equivalent to (R \$X\$ \$Y\$)
	R and RC change all instances of X to Y. The commands R1 and RC1 are available for changing just one, (i.e., the first) instance of X to Y.
(R1 <i>X Y</i> )	[Editor Command]
	Find the first instance of X and replace it by Y.
(RC1 <i>X Y</i> )	[Editor Command]
	(R1 \$X\$ \$Y\$).

16.46 LIST STRUCTURE EDITOR

In addition, while R and RC only operate within the current expression, R1 and RC1 will continue searching, a la the F command, until they find an instance of x, even if the search carries them beyond the current expression.

#### (SW N M)

[Editor Command]

Switches the Nth and Mth elements of the current expression.

For example, if the current expression is (LIST (CONS (CAR X) (CAR Y)) (CONS (CDR X) (CDR Y))), (SW 2 3) will modify it to be (LIST (CONS (CDR X) (CDR Y)) (CONS (CAR X) (CAR Y))). The relative order of N and M is not important, i.e., (SW 3 2) and (SW 2 3) are equivalent.

**SW** uses the generalized **NTH** command (**NTH** *COM*) to find the *N*th and *M*th elements, a la the **BI-BO** commands.

Thus in the previous example, (SW CAR CDR) would produce the same result.

## (SWAP @<sub>1</sub> @<sub>2</sub>)

[Editor Command]

Like SW except switches the expressions specified by  $@_1$  and  $@_2$ , not the corresponding elements of the current expression, i.e.  $@_1$  and  $@_2$  can be at different levels in current expression, or one or both be outside of current expression.

Thus, using the previous example, (SWAP CAR CDR) would result in (LIST (CONS (CDR X) (CAR Y)) (CONS (CAR X) (CDR Y))).

## 16.6 Commands That Print

	Prints the <i>M</i> th element of the current expression as though <b>PRINTLEVEL</b> were set to 2.
(P M)	[Editor Command]
	Prints the current expression as though <b>PRINTLEVEL</b> (page 25.11) were set to 2.
P	[Editor Command]
	Prettyprints the current expression.
PP	[Editor Command]

(P 0)	[Editor Command]
	Same as <b>P</b> .
(P M N)	[Editor Command]
	Prints the Mth element of the current expression as though PRINTLEVEL were set to N.
(P 0 N)	[Editor Command]
	Prints the current expression as though PRINTLEVEL were set to N.
?	[Editor Command]
	Same as (P 0 100).
	have to be a number, e.g., (P COND 3) will work. PP causes all comments to be printed as **COMMENT** (see page 26.43). P and? print as **COMMENT** only those comments that are (top level) elements of the current expression. Lower expressions are not really seen by the editor; the printing command simply sets PRINTLEVEL and calls PRINT.
PP*	[Editor Command]
	Prettyprints current expression, including comments.  PP* is equivalent to PP except that it first resets  **COMMENT**FLG to NIL (see page 26.43).
PPV	[Editor Command]
	Prettyprints the current expression as a variable, i.e., no special treatment for LAMBDA, COND, SETQ, etc., or for CLISP.
PPT	[Editor Command]
	Prettyprints the current expression, printing CLISP translations, if any.
?=	[Editor Command]
	Prints the argument names and corresponding values for the current expression. Analagous to the ? = break command (page 14.7). For example,
	*p (STRPOS "A0???" X N (QUOTE ?) T) *? = X = "A0???" Y = X

START = N
SKIP = (QUOTE?)
ANCHOR = T
TAIL =

The command MAKE (page 16.57) is an imperative form of ? = . It allows the user to specify a change to the element of the current expression that corresponds to a particular argument name.

All printing functions print to the terminal, regardless of the primary output file. All use the readtable T. No printing function ever changes the edit chain. All record the current edit chain for use by \P (page 16.28). All can be aborted with control-E.

# 16.7 Commands for Leaving the Editor

ок	[Editor Command]
	Exits from the editor.
STOP	[Editor Command]
	Exits from the editor with an error. Mainly for use in conjunction with TTY: commands (page 16.51) that the user wants to abort.

Since all of the commands in the editor are errorset protected, the user must exit from the editor via a command. STOP provides a way of distinguishing between a successful and unsuccessful (from the user's standpoint) editing session. For example, if the user is executing (MOVE 3 TO AFTER COND TTY:), and he exits from the lower editor with an OK, the MOVE command will then complete its operation. If the user wants to abort the MOVE command, he must make the TTY: command generate an error. He does this by exiting from the lower editor with a STOP command. In this case, the higher editor's edit chain will not be changed by the TTY: command.

Actually, it is also possible to exit the editor by typing control-D. **STOP** is preferred even if the user is editing at the **EVALQT** level, as it will perform the necessary "wrapup" to insure that the changes made while editing will be undoable.

SAVE

[Editor Command]

Exits from the editor and saves the "state of the edit" on the property list of the function or variable being edited under the property EDIT-SAVE. If the editor is called again on the same

structure, the editing is effectively "continued," i.e., the edit chain, mark list, value of **UNFIND** and **UNDOLST** are restored.

SAVE is necessary only if the user is editing many different expressions; an exit from the editor via OK always saves the state of the edit of that call to the editor on the property list of the atom EDIT, under the property name LASTVALUE. OK also remprops EDIT-SAVE from the property list of the function or variable being edited.

Whenever the editor is entered, it checks to see if it is editing the same expression as the last one edited. In this case, it restores the mark list and UNDOLST, and sets UNFIND to be the edit chain as of the previous exit from the editor. For example:

```
←EDITF(FOO)

EDIT

*P

(LAMBDA (X) (PROG & & LP & & & &))

.
.
.
.
.
*P

(COND & &)
*OK

FOO

←.
. any number of LISPX inputs
. except for calls to the editor
←EDITF(FOO)

EDIT
*P
```

```
(LAMBDA (X) (PROG & & LP & & & &))
*\P
(COND & &)
*
```

Furthermore, as a result of the history feature, if the editor is called on the same expression within a certain number of LISPX inputs (namely, the size of the history list, which can be changed with CHANGESLICE, page 13.21) the state of the edit of that expression is restored, regardless of how many other expressions may have been edited in the meantime. For example:

```
←EDITF(FOO)

EDIT

*

.
.
.
.
.
*P
(COND (& &) (& &) (&) (T &))

*OK
FOO
. a small number of LISPX inputs,
. including editing
.
←EDITF(FOO)

EDIT

*\P
(COND (& &) (& &) (& (A) (T &))
```

Thus the user can always continue editing, including undoing changes from a previous editing session, if (1) No other expressions have been edited since that session (since saving takes place at exit time, intervening calls that were aborted via control-D or exited via STOP will not affect the editor's memory); or (2) That session was "sufficiently" recent; or (3) It was ended with a SAVE command.

# 16.8 Nested Calls to Editor

TTY:

[Editor Command]

Calls the editor recursively. The user can then type in commands, and have them executed. The TTY: command is completed when the user exits from the lower editor. (see OK and STOP above).

The TTY: command is extremely useful. It enables the user to set up a complex operation, and perform interactive attention-changing commands part way through it. For example the command (MOVE 3 TO AFTER COND 3 P TTY:) allows the user to interact, in effect, within the MOVE command. Thus he can verify for himself that the correct location has been found, or complete the specification "by hand." In effect, TTY: says "I'll tell you what you should do when you get there."

The TTY: command operates by printing TTY: and then calling the editor. The initial edit chain in the lower editor is the one that existed in the higher editor at the time the TTY: command was entered. Until the user exits from the lower editor, any attention changing commands he executes only affect the lower editor's edit chain. Of course, if the user performs any structure modification commands while under a TTY: command, these will modify the structure in both editors, since it is the same structure. When the TTY: command finishes, the lower editor's edit chain becomes the edit chain of the higher editor.

	Calls EDITF or EDITV or EDITP on CAR of current expression.
EP	[Editor Command]
EV	[Editor Command]
EF	[Editor Command]

# 16.9 Manipulating the Characters of an Atom or String

RAISE	[Editor Command]
	An edit macro defined as UP followed by (I 1 (U-CASE (## 1))),
	i.e., it raises to upper-case the current expression, or if a tail, the first element of the current expression.
LOWER	[Editor Command]
	Similar to RAISE, except uses L-CASE.
CAP	[Editor Command]
	First does a RAISE, and then lowers all but the first character, i.e., the first character is left capitalized.
	Note: RAISE, LOWER, and CAP are all no-ops if the corresponding atom or string is already in that state.

16.52

(RAISE X)	[Editor Command]
	Equivalent to (I R (L-CASE $X$ ) $X$ ), i.e., changes every lower-case $X$
	to upper-case in the current expression.
(LOWER X)	[Editor Command]
	Similar to RAISE, except performs (I R X (L-CASE X)).
	Note that in both (RAISE X) and (LOWER X), X should be typed in upper case.
REPACK	[Editor Command]
	Permits the "editing" of an atom or string.
	REPACK operates by calling the editor recursively on UNPACK of the current expression, or if it is a list, on UNPACK of its first element. If the lower editor is exited successfully, i.e., via OK as opposed to STOP, the list of atoms is made into a single atom or string, which replaces the atom or string being "repacked." The new atom or string is always printed.
	Example:
	*P
	"THIS IS A LOGN STRING")
	*REPACK
	*EDIT
	P (THIS % IS % A % LOGN % STRING) *(SW G N)
	*ОК
	"THIS IS A LONG STRING" *
	Note that this could also have been accomplished by (R \$GN\$ \$NG\$) or simply (RC GN NG).
(REPACK @)	[Editor Command]
***************************************	Does (LC . @) followed by REPACK, e.g. (REPACK THIS\$).

# 16.10 Manipulating Predicates and Conditional Expressions

JOINC

[Editor Command]

Used to join two neighboring COND's together, e.g. (COND CLAUSE<sub>1</sub> CLAUSE<sub>2</sub>) followed by (COND CLAUSE<sub>3</sub> CLAUSE<sub>4</sub>) becomes (COND CLAUSE<sub>1</sub> CLAUSE<sub>2</sub> CLAUSE<sub>3</sub> CLAUSE<sub>4</sub>). JOINC

does an (F COND T) first so that you don't have to be at the first COND.

#### (SPLITC X)

[Editor Command]

Splits one COND into two. X specifies the last clause in the first COND, e.g. (SPLITC 3) splits (COND CLAUSE<sub>1</sub> CLAUSE<sub>2</sub> CLAUSE<sub>3</sub> CLAUSE<sub>4</sub>) into (COND CLAUSE<sub>1</sub> CLAUSE<sub>2</sub>) (COND CLAUSE<sub>3</sub> CLAUSE<sub>4</sub>). Uses the generalized NTH command (NTH COM), so that X does not have to be a number, e.g., the user can say (SPLITC RETURN), meaning split after the clause containing RETURN. SPLITC also does an (F COND T) first.

#### **NEGATE**

[Editor Command]

Negates the current expression, i.e. performs (MBD NOT), except that is smart about simplifying. For example, if the current expression is: (OR (NULL X) (LISTP X)), NEGATE would change it to (AND X (NLISTP X)).

**NEGATE** is implemented via the function **NEGATE** (page 3.20).

#### **SWAPC**

[Editor Command]

Takes a conditional expression of the form (COND (A B)(T C)) and rearranges it to an equivalent (COND ((NOT A) C)(T B)), or (COND (A B) (C D)) to (COND ((NOT A) (COND (C D))) (T B)).

**SWAPC** is smart about negations (uses **NEGATE**) and simplifying **CONDs**. It always produces an equivalent expression. It is useful for those cases where one wants to insert extra clauses or tests.

# 16.11 History commands in the editor

All of the user's inputs to the editor are stored on the history list EDITHISTORY (see page 13.43, the editor's history list, and all of the programmer's assistant commands for manipulating the history list, e.g. REDO, USE, FIX, NAME, etc., are available for use on events on EDITHISTORY. In addition, the following four history commands are recognized specially by the editor. They always operate on the last, i.e. most recent, event.

#### DO COM

[Editor Command]

Allows the user to supply the command name when it was omitted.

**USE** is useful when a command name is *incorrect*.

For example, suppose the user wants to perform (-2 (SETQ X (LIST Y Z))) but instead types just (SETQ X (LIST Y Z)). The editor will type SETQ?, whereupon the user can type DO -2. The effect is the same as though the user had typed FIX, followed by (LI 1), (-1 -2), and OK, i.e., the command (-2 (SETQ X (LIST Y Z))) is executed. DO also works if the command is a line command.

!F	[Editor Command]
	Same as DO F.
	In the case of !F, the previous command is always treated as though it were a line command, e.g., if the user types (SETQ X &) and then !F, the effect is the same as though he had typed F (SETQ X &), not (F (SETQ X &)).
!E	[Editor Command]
	Same as DO E.
!N	[Editor Command]
	Same as DO N.

# 16.12 Miscellaneous Commands

NIL	[Editor Command]
	Unless preceded by F or BF, is always a no-op. Thus extra right parentheses or square brackets at the ends of commands are ignored.
CL	[Editor Command]
	Clispifies the current expression (see page 21.22).
DW	[Editor Command]
	Dwimifies the current expression (see page 21.18).
IFY	[Editor Command]
	If the current statement is a <b>COND</b> statement (page 9.4), replaces it with an eqivalent <b>IF</b> statement (page 9.5).
GET*	[Editor Command]
	If the current expression is a comment pointer (see page 26.44), reads in the full text of the comment, and replaces the current expression by it.

(\* . X)

[Editor Command]

X is the text of a comment. \* ascends the edit chain looking for a "safe" place to insert the comment, e.g., in a COND clause, after a PROG statement, etc., and inserts (\* . X) after that point, if possible, otherwise before. For example, if the current expression is (FACT (SUB1 N)) in

#### **[COND**

((ZEROP N) 1) (T (ITIMES N (FACT (SUB1 N]

then (\* CALL FACT RECURSIVELY) would insert (\* CALL FACT RECURSIVELY) before the ITIMES expression. If inserted after the ITIMES, the comment would then be (incorrectly) returned as the value of the COND. However, if the COND was itself a PROG statement, and hence its value was not being used, the comment could be (and would be) inserted after the ITIMES expression.

\* does not change the edit chain, but **UNFIND** is set to where the comment was actually inserted.

**GETD** 

[Editor Command]

Essentially "expands" the current expression in line: (1) if (CAR of) the current expression is the name of a macro, expands the macro in line; (2) if a CLISP word, translates the current expression and replaces it with the translation; (3) if CAR is the name of a function for which the editor can obtain a symbolic definition, either in-core or from a file, substitutes the argument expressions for the corresponding argument names in the body of the definition and replaces the current expression with the result; (4) if CAR of the current expression is an open lambda, substitutes the arguments for the corresponding argument names in the body of the lambda, and then removes the lambda and argument list.

Warning: When expanding a function definition or open lambda expression, GETD does a simple substitution of the actual arguments for the formal arguments. Therefore, if any of the function arguments are used in other ways in the function definition (as functions, as record fields, etc.), they will simply be replaced with the actual arguments.

### (MAKEFN (FN . ACTUALARGS) ARGLIST $N_1 N_2$ )

[Editor Command]

The inverse of **GETD**: makes the current expression into a function. *FN* is the function name, *ARGLIST* its arguments. The argument names are substituted for the corresponding argument values in *ACTUALARGS*, and the result becomes the body of the function definition for *FN*. The current expression is then replaced with (*FN*. *ACTUALARGS*).

If  $N_1$  and  $N_2$  are supplied, ( $N_1$  THRU  $N_2$ ) is used rather than the current expression; if just  $N_1$  is supplied, ( $N_1$  THRU -1) is used.

If ARGLIST is omitted, MAKEFN will make up some arguments, using elements of ACTUALARGS, if they are literal atoms, otherwise arguments selected from (X Y Z A B C ...), avoiding duplicate argument names.

Example: If the current expression is (COND ((CAR X) (PRINT Y T)) (T (HELP))), then (MAKEFN (FOO (CAR X) Y) (A B)) will define FOO as (LAMBDA (A B) (COND (A (PRINT B T)) (T (HELP)))) and then replace the current expression with (FOO (CAR X) Y).

#### (MAKE ARGNAME EXP)

[Editor Command]

Makes the value of ARGNAME be EXP in the call which is the current expression, i.e. a ? = command following a MAKE will always print ARGNAME = EXP. For example:

\*p

(JSYS)

\*?=

JSYS[N;AC1,AC2,AC3,RESULTAC]

\*(MAKE N 10)

\*(MAKE RESULTAC 3)

\*P

(JSYS 10 NIL NIL NIL 3)

Q

[Editor Command]

Quotes the current expression, i.e. MBD QUOTE.

D

[Editor Command]

Deletes the current expression, then prints new current expression, i.e. (:) IP.

# 16.13 Commands That Evaluate

Ε

[Editor Command]

Causes the editor to call the Interlisp executive LISPX giving it the next input as argument. Example:

\*E BREAK(FIE FUM)

(FIE FUM)

\*E (FOO)

(FIE BROKEN)

	:
	Note: E only works when when typed in, e.g, (INSERT D BEFORE E) will treat E as a pattern, and search for E.
(E X)	[Editor Command]
	Evaluates $X$ , i.e., performs (EVAL $X$ ), and prints the result on the terminal.
(E X T)	[Editor Command]
	Same as (E x) but does not print.
	The (E X) and (E X T) commands are mainly intended for use by macros and subroutine calls to the editor; the user would probably type in a form for evaluation using the more convenient format of the (atomic) E command.
$(I \subset X_1 \dots X_N)$	[Editor Command]
	Executes the editor command ( $CY_1 Y_N$ ) where $Y_i = (EVAL X_i)$ . If $C$ is not an atom, $C$ is evaluated also.
	Examples:
	(I 3 (GETD 'FOO)) will replace the 3rd element of the current expression with the definition of FOO.
	(I N FOO (CAR FIE)) will attach the value of FOO and CAR of the value of FIE to the end of the current expression.
	(IF = FOOT) will search for an expression EQ to the value of FOO.
	(I (COND ((NULL FLG) '-1) (T 1)) FOO), if FLG is NIL, inserts the value of FOO before the first element of the current expression, otherwise replaces the first element by the value of FOO.
	The I command sets an internal flag to indicate to the structure modification commands <i>not</i> to copy expression(s) when inserting, replacing, or attaching.
EVAL	[Editor Command]
	Does an EVAL of the current expression.
	Note that EVAL, line-feed, and the GO command together effectively allow the user to "single-step" a program through its symbolic definition.
GETVAL	[Editor Command]
	Replaces the current expression by the result of evaluating it.

# $(\#\#COM_1COM_2...COM_N)$

[NLambda NoSpread Function]

An nlambda, nospread function (not a command). Its value is what the current expression would be after executing the edit commands  $COM_1$  ...  $COM_N$  starting from the present edit chain. Generates an error if any of  $COM_1$  thru  $COM_N$  cause errors. The current edit chain is never changed.

Note: The A, B, :, INSERT, REPLACE, and CHANGE commands make special checks for ## forms in the expressions used for inserting or replacing, and use a copy of ## form instead (see page 16.34). Thus, (INSERT (## 3 2) AFTER 1) is equivalent to (I INSERT (COPY (## 3 2)) 'AFTER 1).

Example: (I R 'X (## (CONS .. Z))) replaces all X's in the current expression by the first CONS containing a Z.

The I command is not very convenient for computing an *entire* edit command for execution, since it computes the command name and its arguments separately. Also, the I command cannot be used to compute an atomic command. The following two commands provide more general ways of computing commands.

# $(COMS X_1 ... X_M)$

[Editor Command]

Each  $X_i$  is evaluated and its value is executed as a command.

For example, (COMS (COND (X (LIST 1 X)))) will replace the first element of the current expression with the value of X if non-NIL, otherwise do nothing. The editor command NIL is a no-op (page 16.55).

# (COMSQ $COM_1 ... COM_N$ )

[Editor Command]

Executes COM<sub>1</sub> ... COM<sub>N</sub>.

**COMSQ** is mainly useful in conjunction with the **COMS** command. For example, suppose the user wishes to compute an entire list of commands for evaluation, as opposed to computing each command one at a time as does the **COMS** command. He would then write (**COMS** (**CONS** '**COMSQ** X)) where X computed the list of commands, e.g., (**COMS** (**CONS** '**COMSQ** (**GETP** FOO '**COMMANDS**))).

# 16.14 Commands That Test

## (IF X)

[Editor Command]

Generates an error unless the value of (EVAL X) is true. In other words, if (EVAL X) causes an error or (EVAL X) = NIL, IF will cause an error.

For some editor commands, the occurrence of an error has a well defined meaning, i.e., they use errors to branch on, as COND uses NIL and non-NIL. For example, an error condition in a location specification may simply mean "not this one, try the next." Thus the location specification (IPLUS (E (OR (NUMBERP (## 3)) (ERROR!)) T)) specifies the first IPLUS whose second argument is a number. The IF command, by equating NIL to error, provides a more natural way of accomplishing the same result. Thus, an equivalent location specification is (IPLUS (IF (NUMBERP (## 3)))).

The IF command can also be used to select between two alternate lists of commands for execution.

# $(IF X COMS_1 COMS_2)$

[Editor Command]

If (EVAL X) is true, execute COMS<sub>1</sub>; if (EVAL X) causes an error or is equal to NIL, execute COMS<sub>2</sub>.

Thus IF is equivalent to

(COMS (CONS 'COMSQ (COND ((CAR (NLSETQ (EVAL X))) COMS<sub>1</sub>) (T COMS<sub>2</sub>))))

For example, the command (IF (READP T) NIL (P)) will print the current expression provided the input buffer is empty.

#### $(IF \times COMS_1)$

[Editor Command]

If (EVAL X) is true, execute COMS<sub>1</sub>; otherwise generate an error.

#### (LP $COMS_1 ... COMS_N$ )

[Editor Command]

Repeatedly executes  $COMS_1$  ...  $COMS_N$  until an error occurs.

For example, (LP F PRINT (N T)) will attach a T at the end of every PRINT expression. (LP F PRINT (IF (## 3) NIL ((N T)))) will attach a T at the end of each print expression which does not already have a second argument. The form (## 3) will cause an error if the edit command 3 causes an error, thereby selecting ((N T)) as

the list of commands to be executed. The IF could also be written as (IF (CDDR (##)) NIL ((N T))).

When an error occurs, LP prints N OCCURRENCES where N is the number of times the commands were successfully executed. The edit chain is left as of the last complete successful execution of  $COMS_1 \dots COMS_N$ .

## (LPQ $COMS_1 ... COMS_N$ )

[Editor Command]

## Same as LP but does not print the message N OCCURRENCES.

In order to prevent non-terminating loops, both LP and LPQ terminate when the number of iterations reaches MAXLOOP, initially set to 30. MAXLOOP can be set to NIL, which is equivalent to setting it to infinity. Since the edit chain is left as of the last successful completion of the loop, the user can simply continue the LP command with REDO (page 13.8).

#### (SHOW X)

[Editor Command]

X is a list of patterns. SHOW does a LPQ printing all instances of the indicated expression(s), e.g. (SHOW FOO (SETQ FIE &)) will print all FOO's and all (SETQ FIE &)'s. Generates an error if there aren't any instances of the expression(s).

## (EXAM X)

[Editor Command]

Like **SHOW** except calls the editor recursively (via the TTY: command, see page 16.51) on each instance of the indicated espression(s) so that the user can examine and/or change them.

## $(ORR\ COMS_1 ... COMS_N)$

[Editor Command]

ORR begins by executing COMS<sub>1</sub>, a list of commands. If no error occurs, ORR is finished. Otherwise, ORR restores the edit chain to its original value, and continues by executing COMS<sub>2</sub>, etc. If none of the command lists execute without errors, i.e., the ORR "drops off the end", ORR generates an error. Otherwise, the edit chain is left as of the completion of the first command list which executes without an error.

NIL as a command list is perfectly legal, and will always execute successfully. Thus, making the last "argument" to ORR be NIL will insure that the ORR never causes an error. Any other atom is treated as (ATOM), i.e., the above example could be written as (ORR NX !NX NIL).

For example, (ORR (NX) (!NX) NIL) will perform a NX, if possible, otherwise a !NX, if possible, otherwise do nothing. Similarly, DELETE could be written as (ORR (UP (1)) (BK UP (2)) (UP (: NIL))).

# 16.15 Edit Macros

Many of the more sophisticated branching commands in the editor, such as ORR, IF, etc., are most often used in conjunction with edit macros. The macro feature permits the user to define new commands and thereby expand the editor's repertoire, or redefine existing commands (to refer to the original definition of a built-in command when redefining it via a macro, use the ORIGINAL command, page 16.64).

Macros are defined by using the M command:

# $(M \subset COMS_1 ... COMS_N)$

[Editor Command]

For C an atom, M defines C as an atomic command. If a macro is redefined, its new definition replaces its old. Executing C is then the same as executing the list of commands  $COMS_1 \dots COMS_N$ .

For example, (M BP BK UP P) will define BP as an atomic command which does three things, a BK, and UP, and a P. Macros can use commands defined by macros as well as built in commands in their definitions. For example, suppose Z is defined by (M Z -1 (IF (READP T) NIL (P))), i.e., Z does a -1, and then if nothing has been typed, a P. Now we can define ZZ by (M ZZ -1 Z), and ZZZ by (M ZZZ -1 -1 Z) or (M ZZZ -1 ZZ).

Macros can also define list commands, i.e., commands that take arguments.

## $(M(C)(ARG_1 ... ARG_N)COMS_1 ... COMS_M)$

[Editor Command]

C an atom. M defines C as a list command. Executing ( $CE_1 ... E_N$ ) is then performed by substituting  $E_1$  for  $ARG_1$ , ...  $E_N$  for  $ARG_N$  throughout  $COMS_1$  ...  $COMS_M$ , and then executing  $COMS_1$  ...  $COMS_M$ .

For example, we could define a more general BP by (M (BP) (N) (BK N) UP P). Thus, (BP 3) would perform (BK 3), followed by an UP, followed by a P.

A list command can be defined via a macro so as to take a fixed or indefinite number of "arguments", as with spread vs. nospread functions. The form given above specified a macro with a fixed number of arguments, as indicated by its argument list. If the "argument list" is atomic, the command takes an indefinite number of arguments.

# $(M(C) ARG COMS_1 ... COMS_M)$

[Editor Command]

If C, ARG are both atoms, this defines C as a list command. Executing  $(CE_1 \dots E_N)$  is performed by substituting  $(E_1 \dots E_N)$ , i.e.,

CDR of the command, for ARG throughout  $COMS_1$  ...  $COMS_M$ , and then executing  $COMS_1$  ...  $COMS_M$ .

For example, the command 2ND (page 16.24), could be defined as a macro by (M (2ND) X (ORR ((LC.X) (LC.X)))).

Note that for all editor commands, "built in" commands as well as commands defined by macros as atomic commands and list definitions are *completely* independent. In other words, the existence of an atomic definition for C in no way affects the treatment of C when it appears as CAR of a list command, and the existence of a list definition for C in no way affects the treatment of C when it appears as an atom. In particular, C can be used as the name of either an atomic command, or a list command, or both. In the latter case, two entirely different definitions can be used.

Note also that once C is defined as an atomic command via a macro definition, it will not be searched for when used in a location specification, unless it is preceded by an F. Thus (INSERT -- BEFORE BP) would not search for BP, but instead perform a BK, and UP, and a P, and then do the insertion. The corresponding also holds true for list commands.

Occasionally, the user will want to employ the **S** command in a macro to save some temporary result. For example, the **SW** command could be defined as:

Since this version of SW sets FOO and FIE, using SW may have undesirable side effects, especially when the editor was called from deep in a computation, we would have to be careful to make up unique names for dummy variables used in edit macros, which is bothersome. Furthermore, it would be impossible to define a command that called itself recursively while setting free variables. The BIND command solves both problems.

(BIND  $COMS_1 ... COMS_N$ )

[Editor Command]

Binds three dummy variables #1, #2, #3, (initialized to NIL), and then executes the edit commands  $COMS_1 \dots COMS_N$ . BIND uses a **PROG** to make these bindings, so they are only in effect while the

commands are being executed and BINDs can be used recursively; the variables #1, #2, and #3 will be rebound each time BIND is invoked.

Thus, we can write SW safely as:

```
(M (SW) (N M)
(BIND (NTH N)
(S #1 1)
MARK
0
(NTH M)
(S #2 1)
(I 1 #1)
←←
(I 1 #2)))
```

## (ORIGINAL COMS<sub>1</sub> ... COMS<sub>N</sub>)

[Editor Command]

Executes  $COMS_1$  ...  $COMS_N$  without regard to macro definitions. Useful for redefining a built in command in terms of itself., i.e. effectively allows user to "advise" edit commands.

User macros are stored on a list USERMACROS. The file package command USERMACROS (page 17.34), is available for dumping all or selected user macros.

## 16.16 Undo

Each command that causes structure modification automatically adds an entry to the front of UNDOLST that contains the information required to restore all pointers that were changed by that command.

#### **UNDO**

[Editor Command]

Undoes the last, i.e., most recent, structure modification command that has not yet been undone, and prints the name of that command, e.g., MBD undone. The edit chain is then exactly what it was before the "undone" command had been performed. If there are no commands to undo, UNDO types nothing saved.

## !UNDO

[Editor Command]

Undoes all modifications performed during this editing session, i.e. this call to the editor. As each command is undone, its name

is printed a la UNDO. If there is nothing to be undone, !UNDO prints nothing saved.

Undoing an event containing an I, E, or S command will also undo the side effects of the evaluation(s), e.g., undoing (I 3 (/NCONC FOO FIE)) will not only restore the 3rd element but also restore FOO. Similarly, undoing an S command will undo the set. See the discussion of UNDO in page 13.13. (Note that if the I command was typed directly to the editor, /NCONC would automatically be substituted for NCONC as described in page 13.27.)

Since UNDO and !UNDO cause structure modification, they also add an entry to UNDOLST. However, UNDO and !UNDO entries are skipped by UNDO, e.g., if the user performs an INSERT, and then an MBD, the first UNDO will undo the MBD, and the second will undo the INSERT. However, the user can also specify precisely which commands he wants undone by identifying the corresponding entry. In this case, he can undo an UNDO command, e.g., by typing UNDO UNDO, or undo a !UNDO command, or undo a command other than that most recently performed.

Whenever the user continues an editing session, the undo information of the previous session is protected by inserting a special blip, called an undo-block, on the front of UNDOLST. This undo-block will terminate the operation of a !UNDO, thereby confining its effect to the current session, and will similarly prevent an UNDO command from operating on commands executed in the previous session.

Thus, if the user enters the editor continuing a session, and immediately executes an UNDO or !UNDO, the editor will type BLOCKED instead of NOTHING SAVED. Similarly, if the user executes several commands and then undoes them all, another UNDO or !UNDO will also cause BLOCKED to be typed.

## **UNBLOCK**

[Editor Command]

Removes an undo-block. If executed at a non-blocked state, i.e., if UNDO or !UNDO could operate, types NOT BLOCKED.

### **TEST**

[Editor Command]

Adds an undo-block at the front of UNDOLST.

Note that **TEST** together with **!UNDO** provide a "tentative" mode for editing, i.e., the user can perform a number of changes, and then undo all of them with a single **!UNDO** command.

#### (UNDO EventSpec)

[Editor Command]

EventSpec is an event specification (see page 13.6). Undoes the indicated event on the history list. In this case, the event does not have to be in the current editing session, even if the previous session has not been unblocked as described above. However, the user does have to be editing the same expression as was being edited in the indicated event.

If the expressions differ, the editor types the warning message "different expression," and does not undo the event. The editor enforces this to avoid the user accidentally undoing a random command by giving the wrong event specification.

# 16.17 EDITDEFAULT

Whenever a command is not recognized, i.e., is not "built in" or defined as a macro, the editor calls an internal function, EDITDEFAULT, to determine what action to take. Since EDITDEFAULT is part of the edit block, the user cannot advise or redefine it as a means of augmenting or extending the editor. However, the user can accomplish this via EDITUSERFN. If the value of the variable EDITUSERFN is T, EDITDEFAULT calls the function EDITUSERFN giving it the command as an argument. If EDITUSERFN returns a non-NIL value, its value is interpreted as a single command and executed. Otherwise, the error correction procedure described below is performed.

If a location specification is being executed, an internal flag informs EDITDEFAULT to treat the command as though it had been preceded by an F.

If the command is a list, an attempt is made to perform spelling correction on the CAR of the command (unless DWIMFLG = NIL) using EDITCOMSL, a list of all list edit commands. If spelling correction is successful, the correct command name is RPLACAed into the command, and the editor continues by executing the command. In other words, if the user types (LP F PRINT (MBBD AND (NULL FLG))), only one spelling correction will be necessary to change MBBD to MBD. If spelling correction is not successful, an error is generated.

Note: When a macro is defined via the M command, the command name is added to EDITCOMSA or EDITCOMSL, depending on whether it is an atomic or list command. The USERMACROS file package command is aware of this, and provides for restoring EDITCOMSA and EDITCOMSL.

If the command is atomic, the procedure followed is a little more elaborate.

(1) If the command is one of the list commands, i.e., a member of EDITCOMSL, and there is additional input on the same terminal line, treat the entire line as a single list command. The line is read using READLINE (page 13.36), so the line can be terminated by a square bracket, or by a carriage return not preceded by a space. The user may omit parentheses for any list command typed in at the top level (provided the command is not also an atomic command, e.g. NX, BK). For example,

```
*P
(COND (& &) (T &))
*XTR 3 2]
*MOVE TO AFTER LP
```

If the command is on the list **EDITCOMSL** but no additional input is on the terminal line, an error is generated, e.g.

```
*P
(COND (& &) (T &))
*MOVE
```

#### MOVE?

\*

If the command is on EDITCOMSL, and *not* typed in directly, e.g., it appears as one of the commands in a LP command, the procedure is similar, with the rest of the command stream at that level being treated as "the terminal line", e.g. (LP F (COND (T &)) XTR 2 2).

Note that if the command is being executed in location context, EDITDEFAULT does not get this far, e.g., (MOVE TO AFTER COND XTR 3) will search for XTR, not execute it. However, (MOVE TO AFTER COND (XTR 3)) will work.

(2) If the command was typed in and the first character in the command is an 8, treat the 8 as a mistyped left parenthesis, and and the rest of the line as the arguments to the command, e.g.,

```
*P
(COND (& &) (T &))

*8-2 (Y (RETURN Z)))

= (-2

*P
(COND (Y &) (& &) (T &))
```

(3) If the command was typed in, is the name of a function, and is followed by NIL or a list CAR of which is not an edit command, assume the user forgot to type E and means to apply the function to its arguments, type = E and the function name, and perform the indicated computation, e.g.

```
*BREAK(FOO)
= E BREAK
```

(FOO)

\*

(4) If the last character in the command is **P**, and the first *N*-1 characters comprise a number, assume that the user intended two commands, e.g.,

\*P (COND (& &) (T &)) \*0P = 0 P

- (SETQ X (COND & &))
- (5) Attempt spelling correction using **EDITCOMSA**, and if successful, execute the corrected command.
- (6) If there is additional input on the same line, or command stream, spelling correct using EDITCOMSL as a spelling list, e.g.,
  - \*MBBD SETQ X = MBD
- (6) Otherwise, generate an error.

# 16.18 Editor Functions

(EDIT NAME —)

[Function]

General purpose function for calling the editor. Figures out what type of definition *NAME* has (function, variable, macro, etc.), and calls the editor to edit it. If *NAME* has more than one definition of different types, the user is prompted for which type of definition to edit.

## (EDITF NAME COM 1 COM 2 ... COM N)

[NLambda NoSpread Function]

Nlambda, nospread function for EDITing a Function. NAME is the name of the function,  $COM_1$ ,  $COM_2$ , ...,  $COM_n$  are (optional) edit commands. EDITF returns NAME.

If *NAME* is **NIL**, it defaults to the value of **LASTWORD** (page 20.18), the last function or variable referred to by the user.

Note: **EDITF** initially calls **HASDEF** (page 17.26), which does spelling correction on *NAME* using the spelling list **USERWORDS** (unless **DWIMFLG = NIL**).

The action of **EDITF** is somewhat complicated, because the function may be broken or advised, the expr definition of the function may be saved on the property list of *NAME*, the

- function may need to be loaded from a file, etc. There are many special cases that have to be handled differently. When EDITF is called, it tries the following, in order:
- (1) In the most common case, if the definition of *NAME* is an expr definition (not as a result of its being broken or advised), **EDITE** (page 16.71) is called to edit the function definition.
- (2) If NAME has an expr definition by virtue of its being broken or advised, and the original definition is also an expr definition, then the broken/advised definition is given to EDITE to be edited (since any changes there will also affect the original definition because all changes are destructive). However, a warning message (e.g. "Note: you are editing a BROKEN definition") is printed to alert the user that the function definition is surrounded by a call to BREAK1 or ADV-PROG.
- (3) If NAME has an expr definition by virtue of its being broken or advised, the original definition is not an expr definition, there is no EXPR property, and the file package "knows" which file NAME is contained in (see EDITLOADFNS?, page 16.73), then the expr definition of NAME is loaded onto its property list as described below, and the editor proceeds to the next possibility. Otherwise, a warning message is printed (e.g. "Note: you are editing a BROKEN compiled definition"), and the edit proceeds, e.g., the user may have called the editor to examine the advice on a compiled function.
- (4) If NAME has an expr definition by virtue of its being broken or advised, the original definition is not an EXPR, and there is an EXPR property, then the function is unbroken/unadvised (latter only with user's approval, since the user may really want to edit the advice) and the editor proceeds to the next possibility.
- (5) If NAME does not have an expr definition, but has an EXPR property, EDITF prints prop, and calls EDITE (page 16.71 to edit this saved expr definition. In this case, if the edit completes and no changes have been made, EDITE prints "not changed, so not unsaved." If changes were made, but the value of DFNFLG (page 10.10) is PROP, EDITE prints "changed, but not unsaved." Otherwise if changes were made, EDITE prints unsaved and does an UNSAVEDEF (page 17.28).
- (6) If NAME neither has an expr definition nor an EXPR property, and the file package "knows" which file NAME is contained in (see EDITLOADFNS?, page 16.73), the expr definition of NAME is automatically loaded (using LOADFNS, page 17.6) onto the EXPR property, and EDITE proceeds as described above. Because of the existence of file maps (page 17.55), this operation is extremely fast, essentially requiring only the time to perform the READ to obtain the actual definition. In addition, if NAME is a member of a block, the user will be asked whether he wishes the rest of the functions in the block to be loaded at the same time.

LIST STRUCTURE EDITOR

The editor's behaviour in this case is controlled by the value of EDITLOADFNSFLG, which is a dotted pair of two flags. The CAR of EDITLOADFNSFLG controls the loading of the function, and the CDR controls the loading of the block. A value of NIL for either flag means "load but ask first," a value of T means "don't ask, just do it" and anything else means "don't ask, don't do it." The initial value of EDITLOADFNSFLG is (T . NIL), meaning to load the function without asking, and ask about loading the block.

- (7) If *NAME* has neither an expr definition nor an **EXPR** property, but it does have a macro definition, that definition is edited.
- (8) If NAME has neither an expr definition nor an EXPR property nor a macro definition, the user is prompted with "No FNS defn for NAME. Do you wish to edit a dummy defn?". If the user confirms by typing Yes, a "blank" definition (stored on the variable DUMMY-EDIT-FUNCTION-BODY) is edited. If any changes are made, on exit from the editor, the definition will be installed as the name's function definition. Exiting the editor with the STOP command will prevent any changes to the function definition.
- (9) Otherwise, the editor generates an NAME not editable error.

In all cases, if a function is edited, and changes were made, the function is time-stamped (by EDITE), which consists of inserting a comment of the form (\* USERS-INITIALS DATE) (see page 16.76). If the function was already time-stamped, then only the date is changed.

# (EDITFNS NAME $COM_1 COM_2 ... COM_N$ )

[NLambda NoSpread Function]

An nlambda, nospread function, used to perform the same editing operations on several functions. *NAME* is evaluated to obtain a list of functions. If *NAME* is atomic, and its value is not a list, and it is the name of a file, (FILEFNSLST 'NAME) will be used as the list of functions to be edited.

 $COM_1$ ,  $COM_2$ , ...,  $COM_N$  are (optional) edit commands. EDITFNS maps down the list of functions, prints the name of each function, and calls the editor (via EDITF) on that function. The value of EDITFNS is NIL.

For example, (EDITFNS FOOFNS (R FIE FUM)) will change every FIE to FUM in each of the functions on FOOFNS.

The call to the editor is **ERRORSET** protected (page 14.21), so that if the editing of one function causes an error, **EDITFNS** will proceed to the next function. In particular, if an error occurred while editing a function via its **EXPR** property, the function would not be unsaved. Thus in the above example, if one of the functions did not contain a **FIE**, the **R** command would cause an error, it would not be unsaved, and editing would continue with the next function.

# (EDITV NAME COM<sub>1</sub> COM<sub>2</sub> ... COM<sub>N</sub>)

[NLambda NoSpread Function]

Similar to EDITF, for editing values of variables. NAME is the name of the variable,  $COM_1$ ,  $COM_2$ , ...,  $COM_n$  are (optional) edit commands.

If *NAME* is **NIL**, it defaults to the value of **LASTWORD** (page 20.18), the last function or variable referred to by the user.

If *NAME* is bound as a variable on the stack, EDITV edits its value, otherwise if *NAME* has a top-level variable binding, EDITV edits the top-level value. EDITV returns *NAME* if it is bound or has a top-level value, **NIL** otherwise.

**EDITV** calls **EDITE** (page 16.71) to edit the value of the variable. Note that if the value of the variable is not a list, this causes an error: "*EXPR* not editable."

Note: **EDITV** initially calls **HASDEF** (page 17.26), which does spelling correction on *NAME* using the spelling list **USERWORDS** (unless **DWIMFLG = NIL**).

## (EDITP NAME COM<sub>1</sub> COM<sub>2</sub> ... COM<sub>N</sub>)

[NLambda NoSpread Function]

Similar to EDITF for editing property lists. If the property list of *NAME* is **NIL**, **EDITP** attempts spelling correction using **USERWORDS** (unless **DWIMFLG = NIL**). Then **EDITP** calls **EDITE** on the property list of *NAME*, (or the corrected spelling thereof), with *TYPE* = **PROPLST**.

**EDITP** returns the atom whose property list was edited.

#### (EDITE EXPR COMS ATM TYPE IFCHANGEDFN)

[Function]

Edits the expression, *EXPR*, by calling **EDITL** on (**LIST** *EXPR*) and returning the last element of the value returned by **EDITL**. Generates an error if *EXPR* is not a list: "*EXPR* not editable."

ATM and TYPE are for use in conjunction with the file package. If supplied, ATM is the name of the object that EXPR is associated with, and TYPE describes the association (i.e., TYPE corresponds to the TYPE argument of MARKASCHANGED, page 17.17.) For example, if EXPR is the definition of FOO, ATM = FOO and TYPE = FNS. When EDITE is called from EDITP, EXPR is the property list of ATM, and TYPE = PROPLST, etc.

**EDITE** calls **EDITL** to do the editing (described below). Upon return, if both *ATM* and *TYPE* are non-NIL, ADDSPELL is called to add *ATM* to the appropriate spelling list. Then, if *EXPR* was changed, and the value of *IFCHANGEDFN* is not NIL, the value of *IFCHANGEDFN* is applied to the arguments *ATM*, *EXPR*, *TYPE*, and a flag which is T for normal edits from editor, NIL for calls that were aborted via control-D or **STOP**. Otherwise, if *EXPR* was changed, and the value of *IFCHANGEDFN* is NIL, and *TYPE* is not NIL, MARKASCHANGED (page 17.17) is called on *ATM* and *TYPE*.

**EDITE** uses **RESETSAVE** to insure that *IFCHANGEDFN* and **MARKASCHANGED** are called if any change was made even if editing is subsequently aborted via control-D. (In this case, the fourth argument to *IFCHANGEDFN* will be **NIL**.)

Note: For TYPE = FNS or TYPE = PROP, i.e., calls from EDITF, EDITE performs some additional operations as described earlier under EDITF.

### (EDITL L COMS ATM MESS EDITCHANGES)

[Function]

**EDITL** is the editor. Its first argument is the edit chain, and its value is an edit chain, namely the value of L at the time **EDITL** is exited. L is a **SPECVAR**, and so can be examined or set by edit commands. For example,  $\uparrow$  is equivalent to (E (SETQ L (LAST L)) T). However, the user should only manipulate or examine L directly as a last resort, and then with caution.

COMS is an optional list of commands. For interactive editing, coms is NIL. In this case, EDITL types "edit" (or MESS, if it not NIL) and then waits for input from terminal. All input is done with EDITRDTBL as the read table. Exit occurs only via an OK, STOP, or SAVE command.

If *COMS* is *not* **NIL**, no message is typed, and each member of *COMS* is treated as a command and executed. If an error occurs in the execution of one of the commands, no error message is printed, the rest of the commands are ignored, and **EDITL** exits with an error, i.e., the effect is the same as though a **STOP** command had been executed. If all commands execute successfully, **EDITL** returns the current value of *L*.

ATM is optional. On calls from EDITF, it is the name of the function being edited; on calls from EDITV, the name of the variable, and calls from EDITP, the atom whose property list is being edited. The property list of ATM is used by the SAVE command for saving the state of the edit. Thus SAVE will not save anything if ATM = NIL, i.e., when editing arbitrary expressions via EDITE or EDITL directly.

EDITCHANGES is used for communicating with EDITE.

#### (EDITLO L COMS MESS —)

[Function]

Like EDITL, except it does not rebind or initialize the editor's various state variables, such as LASTAIL, UNFIND, UNDOLST, MARKLST, etc. Should only be called when already under a call to EDITL.

#### (EDIT4E *PAT X* —)

[Function]

The editor's pattern match routine. Returns **T**, if *PAT* matches *X*. See page 16.18 for definition of "match".

Note: Before each search operation in the editor begins, the entire pattern is scanned for atoms or strings containing \$s (<esc>s). Atoms or strings containing \$s are replaced by lists of the form (\$ ...), and atoms or strings ending in double \$s are replaced by lists of the form (\$\$ ...). Thus from the standpoint of EDIT4E, single and double \$ patterns are detected by (CAR PAT) being the atom \$ (<esc>) or the atom \$\$ (<esc>>). Therefore, if the user wishes to call EDIT4E directly, he must first convert any patterns which contain atoms or strings containing \$s to the form recognized by EDIT4E. This is done with the function EDITFPAT:

#### (EDITFPAT PAT —)

[Function]

Makes a copy of *PAT* with all atoms or strings containing \$s (<esc>s) converted to the form expected by EDIT4E.

#### (EDITFINDP X PAT FLG)

[Function]

Allows a program to use the edit find command as a pure predicate from outside the editor. X is an expression, PAT a pattern. The value of EDITFINDP is T if the command F PAT would succeed, NIL otherwise. EDITFINDP calls EDITFPAT to convert PAT to the form expected by EDIT4E, unless FLG = T. Thus, if the program is applying EDITFINDP to several different expressions using the same pattern, it will be more efficient to call EDITFPAT once, and then call EDITFINDP with the converted pattern and FLG = T.

#### (ESUBST NEW OLD EXPR ERRORFLG CHARFLG)

[Function]

Equivalent to performing (R OLD NEW) with EXPR as the current expression, i.e., the order of arguments is the same as for SUBST. Note that OLD and/or NEW can employ \$s (<esc>s). The value of ESUBST is the modified EXPR. Generates an error if OLD not found in EXPR. If ERRORFLG = T, also prints an error message of the form OLD?

If CHARFLG = T and no \$s (<esc>s) are specified in NEW or OLD, it is equivalent to (RC OLD NEW). In other words, if CHARFLG = T, and no \$s appear, ESUBST will supply them.

**ESUBST** is always undoable.

### (EDITLOADFNS? FN STR ASKFLG FILES)

[Function]

FN is the name of a function. EDITLOADFNS? returns the name of file FN is contained in, or NIL if no file is found.

**EDITLOADFNS?** performs (WHEREIS FN 'FNS FILES) to obtain the name of the file(s) containing FN, if any (see page 17.14). If WHEREIS returns more than one file, EDITLOADFNS? asks the user to indicate which file to use.

If the file has been LOADed or LOADFROMed, the file name saved on the FILEDATES property (page 17.20) of the file is checked by calling INFILEP. If not found, FINDFILE is called to find the file. If a file is found, the file date (see FILEDATE, page 17.52) is compared to the file date saved on the FILEDATES property of the file, to determine whether this file is the one that was originally loaded. If not, EDITLOADFNS? prints "\*\*\* note: FILENAME dated DATE isn't current version; FILENAME dated DATE is." and then uses the file found.

In the case that FILES = T and the WHEREIS library package has been loaded, files(s) may be found that have not been loaded or otherwise noticed, and thus will not have FILEDATES property. In this case, EDITLOADFNS? does not do any version checks, but simply uses the latest version.

Having decided which file the function is on, if ASKFLG = NIL, EDITLOADFNS? prints the value of STR followed by the name of the file, and returns the name of the file. If ASKFLG = NIL and STR = NIL, EDITLOADFNS? prints "loading definition of FN from FILENAME."

If ASKFLG = T, EDITLOADFNS? calls ASKUSER (page 26.12) giving (LIST FN STR FILENAME) as the message to be printed. If ASKUSER returns Y, EDITLOADFNS? returns the filename.

**EDITLOADFNS?** is used by the editor, **LOADFNS** (when the file name is not supplied), by **PRETTYPRINT**, and by **DWIM**.

The function EDITCALLERS provides a way of rapidly searching a file or entire set of files, even files not loaded into Interlisp or "noticed" by the file package, for the appearance of one or more key words (atoms) anywhere in the file.

### (EDITCALLERS ATOMS FILES COMS)

[Function]

Uses FFILEPOS to search the file(s) FILES for occurrences of the atom(s) ATOMS. It then calls EDITE on each of those objects, performing the edit commands COMS. If COMS = NIL, then (EXAM . ATOMS) is used. Both ATOMS and FILES may be single atoms. If FILES is NIL, FILELST is used. Elements on ATOMS may contain \$s (<esc>s).

**EDITCALLERS** prints the name of each file as it searches it, and when it finds an occurrence of one of *ATOMS*, it prints out either the name of the containing function or, if the atom occurred outside a function definition, it prints out the byte position at which the atom was found.

**EDITCALLERS** will read in and use the filemap of the file. In the case that the editor is actually called, **EDITCALLERS** will **LOADFROM** the file if the file has not previously been noticed.

**EDITCALLERS** uses **GETDEF** (page 17.25) to obtain the "definition" for each object. When **EDITE** returns, if a change was made, **PUTDEF** is called to store the changed object.

#### (FINDCALLERS ATOMS FILES)

[Function]

Like EDITCALLERS, except does not call the editor, but instead simply returns the list of files that contain one of ATOMS.

#### **EDITRACEFN**

[Variable]

This variable is available to help the user debug complex edit macros, or subroutine calls to the editor. If EDITRACEFN is set to T, the function EDITRACEFN (initially undefined) is called whenever a command that was not typed in by the user is about to be executed, giving it that command as its argument. However, the TRACE and BREAK options described below are probably sufficient for most applications.

If **EDITRACEFN** is set to **TRACE**, the name of the command and the current expression are printed. If **EDITRACEFN** = **BREAK**, the same information is printed, and the editor goes into a break. The user can then examine the state of the editor.

EDITRACEFN is initially NIL.

# (SETTERMCHARS NEXTCHAR BKCHAR LASTCHAR UNQUOTECHAR 2CHAR PPCHAR)

[Function]

Used to set up the immediate read macros used by the editor, as well as the control-Y read macro (page 25.42). *NEXTCHAR*, *BKCHAR*, *LASTCHAR*, *2CHAR* and *PPCHAR* specify which control character should perform the edit commands NXP, BKP, -1P, 2P and PP\*, respectively; *UNQUOTECHAR* corresponds to control-Y. For each non-NIL argument, SETTERMCHARS makes the corresponding control character have the indicated function. The arguments to SETTERMCHARS can be character codes, the control characters themselves, or the alphabetic letters corresponding to the control characters.

If an argument to SETTERMCHARS is currently assigned as an interrupt character, it cannot be a read macro (since the reader will never see it); SETTERMCHARS prints a message to that effect and makes no change to the control character. However, if SETTERMCHARS is given a list as one of its arguments, it uses CAR of the list even if the character is an interrupt. In this case, if CADR of the list is non-NIL, SETTERMCHARS reassigns the interrupt function to CADR. For example, if control-X is an interrupt, (SETTERMCHARS '(X W)) assigns control-W the interrupt control-X had, and makes control-X be the NEXTCHAR operator.

As part of the greeting operation, SETTERMCHARS is applied to the value of EDITCHARACTERS, which is initially (J X Z Y N) in Interlisp-D and in Interlisp-10 under Tenex, (J A L Y K) under Tops-20 (control-J is line-feed). SETTERMCHARS is called *after* the user's init file is loaded, so it works to reset EDITCHARACTERS in the init file; alternatively, SETTERMCHARS can be called explicitly.

# 16.19 Time Stamps

Whenever a function is edited, and changes were made, the function is time-stamped (by EDITE), which consists of inserting a comment of the form (\* USERS-INITIALS DATE). USERS-INITIALS is the value of the variable INITIALS. After greeting (page 12.1), the function SETINITIALS is called. SETINITIALS searches INITIALSLST, a list of elements of the form (USERNAME . INITIALS) or (USERNAME FIRSTNAME INITIALS). If the user's name is found, INITIALS is set accordingly. If the user's name is not found on INITIALSLST, INITIALS is set to the value of DEFAULTINITIALS, initially edited:. Thus, the default is to always time stamp. To suppress time stamping, the user must either include an entry of the form (USERNAME) on INITIALSLST, or set DEFAULTINITIALS to NIL before greeting, i.e. in his user profile, or else, after greeting, explicitly set INITIALS to NIL.

If the user wishes his functions to be time stamped with his initials when edited, he should include a file package command command of the form (ADDVARS (INITIALSLST (USERNAME . INITIALS))) in the user's INIT.LISP file (see page 12.2).

The following three functions may be of use for specialized applications with respect to time-stamping: (FIXEDITDATE EXPR) which, given a lambda expression, inserts or smashes a time-stamp comment; (EDITDATE? COMMENT) which returns T if COMMENT is a time stamp; and (EDITDATE OLDATE INITLS) which returns a new time-stamp comment. If OLDATE is a time-stamp comment, it will be reused.

TOC.2

Warning: The subsystem within the Interlisp-D environment used for managing collections of definitions (of functions, variables, etc.) is known as the "File Package." This terminology is confusing, because the word, "file" is also used in the more conventional sense as meaning a collection of data stored some physical media. Unfortunately, it is not possible to change this terminology at this time, because many functions and variables (MAKEFILE, FILEPKGTYPES, etc.) incorporate the word "file" in their names. Eventually, the system and the documentation will be revamped to consistantly use the term "module" or "definition group" or "defgroup."

Most implementations of Lisp treat symbolic files as unstructured text, much as they are treated in most conventional programming environments. Function definitions are edited with a character-oriented text editor, and then the changed definitions (or sometimes the entire file) is read or compiled to install those changes in the running memory image. Interlisp incorporates a different philosophy. A symbolic file is considered as a database of information about a group of data values, objects---function definitions, variable declarations, etc. The text in a symbolic file is never edited Definitions are edited only after their textual representations on files have been converted to data-structures that reside inside the Lisp address space. The programs for editing definitions inside Interlisp can therefore make use of the full set of data-manipulation capabilities that the environment already provides, and editing operations can be easily intermixed with the processes of evaluation and compilation.

Interlisp is thus a "resident" programming environment, and as such it provides facilities for moving definitions back and forth between memory and the external databases on symbolic files, and for doing the bookkeeping involved when definitions on many symbolic files with compiled counterparts are being manipulated. The file package provides those capabilities. It removes from the user the burden of keeping track of where things are and what things have changed. The file package also keeps track of which files have been modified and need to be updated and recompiled.

The file package is integrated into many other system packages. For example, if only the compiled version of a file is loaded and the user attempts to edit a function, the file package will attempt to load the source of that function from the appropriate symbolic file. In many cases, if a datum is needed by some

program, the file package will automatically retrieve it from a file if it is not already in the user's working environment.

Some of the operations of the file package are rather complex. For example, the same function may appear in several different files, or the symbolic or compiled files may be in different directories, etc. Therefore, this chapter does not document how the file package works in each and every situation, but instead makes the deliberately vague statement that it does the "right" thing with respect to keeping track of what has been changed, and what file operations need to be performed in accordance with those changes.

For a simple illustration of what the file package does, suppose that the symbolic file FOO contains the functions FOO1 and FOO2, and that the file BAR contains the functions BAR1 and BAR2. These two files could be loaded into the environment with the function LOAD:

←(LOAD 'FOO)

FILE CREATED 4-MAR-83 09:26:55

FOOCOMS

{DSK}FOO.;1

←(LOAD 'BAR)

FILE CREATED 4-MAR-83 09:27:24

BARCOMS

{DSK}BAR.;1

Now, suppose that we change the definition of FOO2 with the editor, and we define two new functions, NEW1 and NEW2. At that point, the file package knows that the in-memory definition of FOO2 is no longer consistent with the definition in the file FOO, and that the new functions have been defined but have not yet been associated with a symbolic file and saved on permanent storage. The function FILES? summarizes this state of affairs and enters into an interactive dialog in which we can specify what files the new functions are to belong to.

### ← (FILES?)

FOO...to be dumped.

plus the functions: NEW1,NEW2 want to say where the above go? Yes

(functions)

NEW1 File name: BAR NEW2 File name: ZAP

new file? Yes

NIL

The file package knows that the file FOO has been changed, and needs to be dumped back to permanent storage. This can be done with MAKEFILE.

←(MAKEFILE 'FOO) {DSK}FOO.;2

Since we added **NEW1** to the old file **BAR** and established a new file **ZAP** to contain **NEW2**, both **BAR** and **ZAP** now also need to be dumped. This is confirmed by a second call to **FILES?**:

← (FILES?)

BAR, ZAP...to be dumped.

FOO...to be listed.

FOO...to be compiled

NIL

We are also informed that the new version we made of FOO needs to be listed (sent to a printer) and that the functions on the file must be compiled.

Rather than doing several MAKEFILEs to dump the files BAR and ZAP, we can simply call CLEANUP. Without any further user interaction, this will dump any files whose definitions have been modified. CLEANUP will also send any unlisted files to the printer and recompile any files which need to be recompiled. CLEANUP is a useful function to use at the end of a debugging session. It will call FILES? if any new objects have been defined, so the user does not lose the opportunity to say explicitly where those belong. In effect, the function CLEANUP executes all the operations necessary to make the user's permanent files consistent with the definitions in his current core-image.

#### ← (CLEANUP)

FOO...compiling {DSK}FOO.;2

BAR...compiling {DSK}BAR.;2

ZAP...compiling {DSK}ZAP.;1

In addition to the definitions of functions, symbolic files in Interlisp can contain definitions of a variety of other types, e.g. variable values, property lists, record declarations, macro definitions, hash arrays, etc. In order to treat such a diverse assortment of data uniformly from the standpoint of file operations, the file package uses the concept of a typed definition, of which a function definition is just one example. A typed definition associates with a name (usually a litatom), a definition of a given type (called the file package type). Note that the same name may have several definitions of different types. For example, a litatom may have both a function

definition and a variable definition. The file package also keeps track of the files that a particular typed definition is stored on, so one can think of a typed definition as a relation between four elements: a name, a definition, a type, and a file.

Symbolic files on permanent storage devices are referred to by names that obey the naming conventions of those devices, usually including host, directory, and version fields. When such definition groups are noticed by the file package, they are assigned simple root names and these are used by all file package operations to refer to those groups of definitions. The root name for a group is computed from its full permanent storage name by applying the function ROOTFILENAME; this strips off the host, directory, version, etc., and returns just the simple name field of the file. For each file, the file package also has a data structure that describes what definitions it contains. This is known as the commands of the file, or its "filecoms". By convention, the filecoms of a file whose root name is X is stored as the value of the litatom XCOMS. For example, the value of FOOCOMS is the filecoms for the file FOO. This variable can be directly manipulated, but the file package contains facilities such as FILES? which make constructing and updating filecoms easier, and in some cases automatic. See page 17.48.

The file package is able to maintain its databases of information because it is notified by various other routines in the system when events take place that may change that database. A file is "noticed" when it is loaded, or when a new file is stored (though there are ways to explicitly notice files without completely loading all their definitions). Once a file is noticed, the file package takes it into account when modifying filecoms, dumping files, etc. The file package also needs to know what typed definitions have been changed or what new definitions have been introduced, so it can determine which files need to be updated. This is done by "marking changes". All the system functions that perform file package operations (LOAD, TCOMPL, PRETTYDEF, etc.), as well as those functions that define or change data, (EDITF, EDITV, EDITP, DWIM corrections to user functions) interact with the file package. Also, typed-in assignment of variables or property values is noticed by the file package. (Note that modifications to variable or property values during the execution of a function body are not noticed.) In some cases the marking procedure can be subtle, e.g. if the user edits a property list using EDITP, only those properties whose values are actually changed (or added) are marked.

All file package operations can be disabled with FILEPKGFLG.

FILEPKGFLG [Variable]

The file package can be disabled by setting **FILEPKGFLG** to **NIL**. This will turn off noticing files and marking changes. **FILEPKGFLG** is initially **T**.

The rest of this chapter goes into further detail about the file package. Functions for loading and storing symbolic files are presented first, followed by functions for adding and removing typed definitions from files, moving typed definitions from one file to another, determining which file a particular definition is stored in, and so on.

# 17.1 Loading Files

The functions below load information from symbolic files into the Interlisp environment. A symbolic file contains a sequence of Interlisp expressions that can be evaluated to establish specified typed definitions. The expressions on symbolic files are read using FILERDTBL as the read table.

The loading functions all have an argument LDFLG. LDFLG affects the operation of DEFINE, DEFINEQ, RPAQ, RPAQ?, and RPAQQ. While a source file is being loaded, DFNFLG (page 10.10) is rebound to LDFLG. Thus, if LDFLG = NIL, and a function is redefined, a message is printed and the old definition saved. If LDFLG = T, the old definition is simply overwritten. If LDFLG = PROP, the functions are stored as "saved" definitions on the property lists under the property EXPR instead of being installed as the active definitions. If LDFLG = ALLPROP, not only function definitions but also variables set by RPAQQ, RPAQ, RPAQ? are stored on property lists (except when the variable has the value NOBIND, in which case they are set to the indicated value regardless of DFNFLG).

Another option is available for users who are loading systems for others to use and who wish to suppress the saving of information used to aid in development and debugging. If LDFLG = SYSLOAD, LOAD will: (1) Rebind DFNFLG to T, so old definitions are simply overwritten; (2) Rebind LISPXHIST to NIL, thereby making the LOAD not be undoable and eliminating the cost of saving undo information (See page 13.25); (3) Rebind ADDSPELLFLG to NIL, to suppress adding to spelling lists; (4) Rebind FILEPKGFLG to NIL, to prevent the file from being "noticed" by the file package; (5) Rebind BUILDMAPFLG to NIL, to prevent a file map from being constructed; (6) After the load has completed, set the filecoms variable and any filevars

variables to **NOBIND**; and (7) Add the file name to **SYSFILES** rather than **FILELST**.

Note: A filevars variable is any variable appearing in a file package command of the form (FILECOM \* VARIABLE) (see page 17.44). Therefore, if the filecoms includes (FNS \* FOOFNS), FOOFNS is set to NOBIND. If the user wants the value of such a variable to be retained, even when the file is loaded with LDFLG = SYSLOAD, then he should replace the variable with an equivalent, non-atomic expression, such as (FNS \* (PROGN FOOFNS)).

All functions that have *LDFLG* as an argument perform spelling correction using **LOADOPTIONS** as a spelling list when *LDFLG* is not a member of **LOADOPTIONS**. **LOADOPTIONS** is initially (NIL T PROP ALLPROP SYSLOAD).

#### (LOAD FILE LDFLG PRINTFLG)

[Function]

Reads successive expressions from *FILE* (with **FILERDTBL** as read table) and evaluates each as it is read, until it reads either **NIL**, or the single atom **STOP**. Note that **LOAD** can be used to load both symbolic and compiled files. Returns *FILE* (full name).

If *PRINTFLG* = T, LOAD prints the value of each expression; otherwise it does not.

# (LOAD? FILE LDFLG PRINTFLG)

[Function]

Similar to LOAD except that it does not load FILE if it has already been loaded, in which case it returns NIL.

Note: LOAD? loads FILE except when the same version of the file has been loaded (either from the same place, or from a copy of it from a different place). Specifically, LOAD? considers that FILE has already been loaded if the full name of FILE is on LOADEDFILELST (page 17.20) or the date stored on the FILEDATES property of the root file name of FILE is the same as the FILECREATED expression on FILE.

#### (LOADFNS FNS FILE LDFLG VARS)

[Function]

Permits selective loading of definitions. FNS is a list of function names, a single function name, or T, meaning to load all of the functions on the file. FILE can be either a compiled or symbolic file. If a compiled definition is loaded, so are all compiler-generated subfunctions. The interpretation of LDFLG is the same as for LOAD.

If FILE = NIL, LOADFNS will use WHEREIS (page 17.14) to determine where the first function in FNS resides, and load from that file. Note that the file must previously have been "noticed" (see page 17.19). If WHEREIS returns NIL, and the WHEREIS

library package has been loaded, **LOADFNS** will use the WHEREIS data base to find the file containing *FN*.

VARS specifies which non-DEFINEQ expressions are to be loaded (i.e., evaluated). It is interpreted as follows:

T Means to load all non-DEFINEQ expressions.

NIL Means to load none of the non-DEFINEQ expressions.

Means to evaluate all variable assignment expressions (beginning with RPAQ, RPAQQ, or RPAQ?, see page 17.54).

Any other litatom

Means the same as specifying a list containing that atom.

A list

VARS

If VARS is a list that is not a valid function definition, each element in VARS is "matched" against each non-DEFINEQ expression, and if any elements in VARS "match" successfully, the expression is evaluated. "Matching" is defined as follows: If an element of VARS is an atom, it matches an expression if it is EQ to either the CAR or the CADR of the expression. If an element of VARS is a list, it is treated as an edit pattern (page 16.18), and matched with the entire expression (using EDIT4E, page 16.72). For example, if VARS was (FOOCOMS DECLARE: (DEFLIST & (QUOTE MACRO))), this would cause (RPAQQ FOOCOMS ...), all DECLARE:s, and all DEFLISTs which set up MACROs to be read and evaluated.

A function definition

If VARS is a list and a valid function definition ((FNTYP VARS) is true), then LOADFNS will invoke that function on every non-DEFINEQ expression being considered, applying it to two arguments, the first and second elements in the expression. If the function returns NIL, the expression will be skipped; if it returns a non-NIL litatom (e.g. T), the expression will be evaluated; and if it returns a list, this list is evaluated instead of the expression. Note: The file pointer is set to the very beginning of the expression before calling the VARS function definition, so it may read the entire expression if necessary. If the function returns a litatom, the file pointer is reset and the expression is READ or SKREAD. However, the file pointer is not reset when the function returns a list, so the function must leave it set immediately after the expression that it has presumably read.

**LOADFNS** returns a list of: (1) The names of the functions that were found; (2) A list of those functions not found (if any) headed by the litatom **NOT-FOUND**:; (3) All of the expressions that were evaluated; (4) A list of those members of *VARS* for which no corresponding expressions were found (if any), again headed by the litatom **NOT-FOUND**:. For example,

← (LOADFNS '(FOO FIE FUM) FILE NIL '(BAZ (DEFLIST &)))

(FOO FIE (NOT-FOUND: FUM) (RPAQ BAZ ...) (NOT-FOUND:
(DEFLIST &)))

# (LOADVARS VARS FILE LDFLG)

[Function]

Same as (LOADFNS NIL FILE LDFLG VARS).

### (LOADFROM FILE FNS LDFLG)

[Function]

Same as (LOADFNS FNS FILE LDFLG T).

Once the file package has noticed a file, the user can edit functions contained in the file without explicitly loading them. Similarly, those functions which have not been modified do not have to be loaded in order to write out an updated version of the file. Files are normally noticed (i.e., their contents become known to the file package; see page 17.19) when either the symbolic or compiled versions of the file are loaded. If the file is not going to be loaded completely, the preferred way to notice it is with LOADFROM. Note that the user can also load some functions at the same time by giving LOADFROM a second argument, but it is normally used simply to inform the file package about the existence and contents of a particular file.

# (LOADBLOCK FN FILE LDFLG)

[Function]

Calls LOADFNS on those functions contained in the block declaration containing FN (See page 18.17). LOADBLOCK is designed primarily for use with symbolic files, to load the EXPRs for a given block. It will not load a function which already has an in-core EXPR definition, and it will not load the block name, unless it is also one of the block functions.

#### (LOADCOMP FILE LDFLG)

[Function]

Performs all operations on *FILE* associated with compilation, i.e. evaluates all expressions under a DECLARE: EVAL@COMPILE (see page 17.40), and "notices" the function and variable names by adding them to the lists NOFIXFNSLST and NOFIXVARSLST (see page 21.21).

Thus, if building a system composed of many files with compilation information scattered among them, all that is required to compile one file is to LOADCOMP the others.

# (LOADCOMP? FILE LDFLG)

[Function]

Similar to LOADCOMP, except it does not load if file has already been loaded (with LOADCOMP), in which case its value is NIL.

Note: LOADCOMP? will load the file even if it has been loaded with LOAD, LOADFNS, etc. The only time it will not load the file is if the file has already been loaded with LOADCOMP.

**FILESLOAD** provides an easy way for the user to load a series of files, setting various options:

Loads the files  $FILE_1$  ...  $FILE_N$  (all arguments unevaluated). If any of these arguments are lists, they specify certain loading options for all following files (unless changed by another list). Within these lists, the following commands are recognized:

#### FROM DIR

Search the specified directories for the file. *DIR* can either be a single directory, or a list of directories to search in order. For example, (FILESLOAD (FROM {ERIS}<LISPCORE>SOURCES>) ...) will search the directory {ERIS}<LISPCORE>SOURCES> for the files. If this is not specified, the default is to search the contents of DIRECTORIES (page 24.31).

If FROM is followed by the key word VALUEOF, the following word is evaluated, and the value is used as the list of directories to search. For example, (FILESLOAD (FROM VALUEOF FOO) ...) will search the directory list that is the value of the variable FOO.

As a special case, if *DIR* is a litatom, and the litatom *DIRDIRECTORIES* is bound, the value of this variable is used as the directory search list. For example, since the variable LISPUSERSDIRECTORIES (page 24.32) is commonly used to contain a list of directories containing "library" packages, (FILESLOAD (FROM LISPUSERS) ...) can be used instead of (FILESLOAD (FROM VALUEOF LISPUSERSDIRECTORIES) ...)

Note: If a FILESLOAD is read and evaluated while loading a file, and it doesn't contain a FROM expression, the default is to search the directory containing the FILESLOAD expression before the value of DIRECTORIES. FILESLOAD expressions can be dumped on files using the FILES file package command (page 17.39).

#### **SOURCE**

Load the source version of the file rather than the compiled version.

### COMPILED

Load the compiled version of the file.

Note: If **COMPILED** is specified, the compiled version will be loaded, if it is found. The source will not be loaded. If neither **SOURCE** or **COMPILED** is specified, the compiled version of the file will be loaded if it is found, otherwise the source will be loaded if it is found.

LOAD

Load the file by calling LOAD, if it has not already been loaded. This is the default unless LOADCOMP or LOADFROM is specified.

Note: If LOAD is specified, FILESLOAD considers that the file has already been loaded if the root name of the file has a non-NIL FILEDATES property. This is a somewhat different algorithm than LOAD? uses. In particular, FILESLOAD will not load a newer version of a file that has already been loaded.

**LOADCOMP** 

Load the file with LOADCOMP? rather than LOAD. Automatically implies SOURCE.

**LOADFROM** 

Load the file with LOADFROM rather than LOAD.

NIL

Т

PROP ALLPROP

SYSLOAD

The loading function is called with its *LDFLG* argument set to the specified token (see page 17.5). *LDFLG* affects the operation of the loading functions by resetting **DFNFLG** (page 10.10) to *LDFLG* during the loading. If none of these tokens are specified, the value of the variable *LDFLG* is used if it is bound, otherwise **NIL** is used.

#### **NOERROR**

If **NOERROR** is specified, no error occurs when a file is not found.

Each list determines how all further files in the lists are loaded, unless changed by another list. The tokens above can be joined together in a single list. For example,

(FILESLOAD (LOADCOMP) NET (SYSLOAD FROM VALUEOF NEWDIRECTORIES) CJSYS)

will call LOADCOMP? to load the file NET searching the value of DIRECTORIES, and then call LOADCOMP? to load the file CJSYS with LDFLG set to SYSLOAD, searching the directory list that is the value of the variable NEWDIRECTORIES.

FILESLOAD expressions can be dumped on files using the FILES file package command (page 17.39).

# 17.2 Storing Files

### (MAKEFILE FILE OPTIONS REPRINTFNS SOURCEFILE)

[Function]

Makes a new version of the file *FILE*, storing the information specified by *FILE*'s filecoms. Notices *FILE* if not previously noticed (see page 17.19). Then, it adds *FILE* to NOTLISTEDFILES and NOTCOMPILEDFILES.

OPTIONS is a litatom or list of litatoms which specify options. By specifying certain options, MAKEFILE can automatically compile or list FILE. Note that if FILE does not contain any function definitions, it is not compiled even when OPTIONS specifies C or RC. The options are spelling corrected using the list MAKEFILEOPTIONS. If spelling correction fails, MAKEFILE generates an error. The options are interpreted as follows:

C RC

After making *FILE*, **MAKEFILE** will compile *FILE* by calling **TCOMPL** (if **C** is specified) or **RECOMPILE** (if **RC** is specified). If there are any block declarations specified in the filecoms for *FILE*, **BCOMPL** or **BRECOMPILE** will be called instead.

If F, ST, STF, or S is the *next* item on *OPTIONS* following C or RC, it is given to the compiler as the answer to the compiler's question **LISTING?** (see page 18.1). For example, (MAKEFILE 'FOO '(C F LIST)) will dump FOO, then TCOMPL or BCOMPL it specifying that functions are not to be redefined, and finally list the file.

LIST After making FILE, MAKEFILE calls LISTFILES to print a hardcopy listing of FILE.

CLISPIFY MAKEFILE calls PRETTYDEF with CLISPIFYPRETTYFLG = T (see page 21.26). This causes CLISPIFY to be called on each function defined as an EXPR before it is prettyprinted.

Alternatively, if FILE has the property FILETYPE with value CLISP or a list containing CLISP, PRETTYDEF is called with CLISPIFYPRETTYFLG reset to CHANGES, which will cause CLISPIFY to be called on all functions marked as having been changed. If FILE has property FILETYPE with value CLISP, the compiler will DWIMIFY its functions before compiling them (see page 18.11).

**FAST** MAKEFILE calls PRETTYDEF with PRETTYFLG = NIL (see page 26.48). This causes data objects to be printed rather than prettyprinted, which is much faster.

**REMAKE** MAKEFILE "remakes" *FILE*: The prettyprinted definitions of functions that have not changed are copied from an earlier version of the symbolic file. Only those functions that have changed are prettyprinted. See page 17.15.

NEW MAKEFILE does not remake FILE. If MAKEFILEREMAKEFLG = T (the initial setting), the default for all calls to MAKEFILE is to remake. The NEW option can be used to override this default.

REPRINTENS and SOURCEFILE are used when remaking a file, as described on page 17.15.

Note: FILE is not added to NOTLISTEDFILES if FILE has on its property list the property FILETYPE with value DON'TLIST, or a list containing DON'TLIST. FILE is not added to NOTCOMPILEDFILES if FILE has on its property list the property FILETYPE with value DON'TCOMPILE, or a list containing DON'TCOMPILE. Also, if FILE does not contain any function definitions, it is not added to NOTCOMPILEDFILES, and it is not compiled even when OPTIONS specifies C or RC.

If a remake is *not* being performed, MAKEFILE checks the state of *FILE* to make sure that the entire source file was actually LOADed. If *FILE* was loaded as a compiled file, MAKEFILE prints the message CAN'T DUMP: ONLY THE COMPILED FILE HAS BEEN LOADED. Similarly, if only some of the symbolic definitions were loaded via LOADFNS or LOADFROM, MAKEFILE prints CAN'T DUMP: ONLY SOME OF ITS SYMBOLICS HAVE BEEN LOADED. In both cases, MAKEFILE will then ask the user if it should dump

anyway; if the user declines, MAKEFILE does not call PRETTYDEF, but simply returns (FILE NOT DUMPED) as its value.

The user can indicate that FILE must be block compiled together with other files as a unit by putting a list of those files on the property list of each file under the property FILEGROUP. If FILE has a FILEGROUP property, the compiler will not be called until all files on this property have been dumped that need to be.

MAKEFILE operates by rebinding PRETTYFLG, PRETTYTRANFLG, and CLISPIFYPRETTYFLG, evaluating each expression on MAKEFILEFORMS (under errorset protection), and then calling PRETTYDEF (page 17.50).

Note: PRETTYDEF calls PRETTYPRINT with its second argument PRETTYDEFLG = T, so whenever PRETTYPRINT (and hence MAKEFILE) start printing a new function, the name of that function is printed if more than 30 seconds (real time) have elapsed since the last time it printed the name of a function.

### (MAKEFILES OPTIONS FILES)

[Function]

Performs (MAKEFILE FILE OPTIONS) for each file on FILES that needs to be dumped. If FILES = NIL, FILELST is used. For example, (MAKEFILES 'LIST) will make and list all files that have been changed. In this case, if any typed definitions for any items have been defined or changed and they are not contained in one of the files on FILELST, MAKEFILES calls ADDTOFILES? to allow the user to specify where these go. MAKEFILES returns a list of all files that are made.

### (CLEANUP FILE 1 FILE 2 ... FILE N)

[NLambda NoSpread Function]

Dumps, lists, and recompiles (with RECOMPILE or BRECOMPILE) any of the specified files (unevaluated) requiring the corresponding operation. If no files are specified, FILELST is used. CLEANUP returns NIL.

**CLEANUP** uses the value of the variable **CLEANUPOPTIONS** as the *OPTIONS* argument to **MAKEFILE**. **CLEANUPOPTIONS** is initially **(RC)**, to indicate that the files should be recompiled. If **CLEANUPOPTIONS** is set to **(RC F)**, no listing will be performed, and no functions will be redefined as the result of compiling. Alternatively, if *FILE*<sub>1</sub> is a list, it will be interpreted as the list of options regardless of the value of **CLEANUPOPTIONS**.

#### (FILES?)

[Function]

Prints on the terminal the names of those files that have been modified but not dumped, dumped but not listed, dumped but not compiled, plus the names of any functions and other typed definitions (if any) that are not contained in any file. If there are

any, FILES? then calls ADDTOFILES? to allow the user to specify where these go.

#### (ADDTOFILES? —)

[Function]

Called from MAKEFILES, CLEANUP, and FILES? when there are typed definitions that have been marked as changed which do not belong to any file. ADDTOFILES? lists the names of the changed items, and asks the user if he wants to specify where these items should be put. If user answers N(o), ADDTOFILES? returns NIL without taking any action. If the user answers ], this is taken to be an answer to each question that would be asked, and all the changed items are marked as dummy items to be ignored. Otherwise, ADDTOFILES? prints the name of each changed item, and accepts one of the following responses:

# A file name A filevar

If the user gives a file name or a variable whose value is a list (a filevar), the item is added to the corresponding file or list, using **ADDTOFILE**.

If the user response is not the name of a file on FILELST or a variable whose value is a list, the user will be asked whether it is a new file. If he says no, then ADDTOFILES? will check whether the item is the name of a list, i.e. whether its value is a list. If not, the user will be asked whether it is a new list.

#### line-feed

Same as the user's previous response.

# space carriage return

Take no action.

- 1 The item is marked as a dummy item by adding it to NILCOMS.

  This tells the file package simply to ignore this item.
- [ The "definition" of the item in question is prettyprinted to the terminal, and then the user is asked again about its disposition.
- ( ADDTOFILES? prompts with "LISTNAME: (", the user types in the name of a list, i.e. a variable whose value is a list, terminated by a ). The item will then only be added to (under) a command in which the named list appears as a filevar. If none are found, a message is printed, and the user is asked again. For example, the user defines a new function FOO3, and when asked where it goes, types (FOOFNS). If the command (FNS \* FOOFNS) is found, FOO3 will be added to the value of FOOFNS. If instead the user types (FOOCOMS), and the command (COMS \* FOOCOMS) is found, then FOO3 will be added to a command for durnping functions that is contained in FOOCOMS.

Note: If the named list is not also the name of a file, the user can simply type it in without parenthesis as described above.

@ ADDTOFILES? prompts with "Near: (", the user types in the name of an object, and the item is then inserted in a command for dumping objects (of its type) that contains the indicated name. The item is inserted immediately after the indicated name.

# (LISTFILES FILE<sub>1</sub> FILE<sub>2</sub> ... FILE<sub>N</sub>)

#### [NLambda NoSpread Function]

Lists each of the specified files (unevaluated). If no files are given, NOTLISTEDFILES is used. Each file listed is removed from NOTLISTEDFILES if the listing is completed. For each file not found, LISTFILES prints the message "FILENAME NOT FOUND" and proceeds to the next file.

LISTFILES calls the function LISTFILES1 on each file to be listed. Normally, LISTFILES1 is defined to simply call SEND.FILE.TO.PRINTER (page 29.1), but the user can advise or redefine LISTFILES1 for more specialized applications.

Any lists inside the argument list to LISTFILES are interpreted as property lists that set the various printing options, such as the printer, number of copies, banner page name, etc (see page 29.1). Later properties override earlier ones. For example,

### (LISTFILES FOO (HOST JEDI) FUM (#COPIES 3) FIE)

will cause one copy of FOO to be printed on the default printer, and 1 copy of FUM and 3 copies of FIE to be printed on the printer JEDI.

# (COMPILEFILES FILE 1 FILE 2 ... FILE N)

## [NLambda NoSpread Function]

Executes the RC and C options of MAKEFILE for each of the specified files (unevaluated). If no files are given, NOTCOMPILEDFILES is used. Each file compiled is removed from NOTCOMPILEDFILES. If FILE<sub>1</sub> is a list, it is interpreted as the OPTIONS argument to MAKEFILES. This feature can be used to supply an answer to the compiler's LISTING? question, e.g., (COMPILEFILES (STF)) will compile each file on NOTCOMPILEDFILES so that the functions are redefined without the EXPRs definitions being saved.

#### (WHEREIS NAME TYPE FILES FN)

#### [Function]

TYPE is a file package type. WHEREIS sweeps through all the files on the list FILES and returns a list of all files containing NAME as a TYPE. WHEREIS knows about and expands all file package commands and file package macros. TYPE = NIL defaults to FNS (to retrieve function definitions). If FILES is not a list, the value of FILELST is used.

If FN is given, it should be a function (with arguments NAME, FILE, and TYPE) which is applied for every file in FILES that contains NAME as a TYPE. In this case, WHEREIS returns NIL.

If the WHEREIS library package has been loaded, WHEREIS is redefined so that FILES = T means to use the whereis package

data base, so **WHEREIS** will find *NAME* even if the file has not been loaded or noticed. *FILES* = **NIL** always means use **FILELST**.

# 17.3 Remaking a Symbolic File

Most of the time that a symbolic file is written using MAKEFILE, only a few of the functions that it contains have been changed since the last time the file was written. Rather than prettprinting all of the functions, it is often considerably faster to "remake" the file, copying the prettprinted definitions of unchanged functions from an earlier version of the symbolic file, and only prettyprinting those functions that have been changed.

MAKEFILE will remake the symbolic file if the REMAKE option is specified. If the NEW option is given, the file is not remade, and all of the functions are prettprinted. The default action is specified by the value of MAKEFILEREMAKEFLG: if T (its initial value), MAKEFILE will remake files unless the NEW option is given; if NIL, MAKEFILE will not remake unless the REMAKE option is given.

Note: If the file has never been loaded or dumped, for example if the filecoms were simply set up in memory, then MAKEFILE will never attempt to remake the file, regardless of the setting of MAKEFILEREMAKEFLG, or whether the REMAKE option was specified.

When MAKEFILE is remaking a symbolic file, the user can explicitly indicate the functions which are to be prettyprinted and the file to be used for copying the rest of the function definitions from via the REPRINTFNS and SOURCEFILE arguments to MAKEFILE. Normally, both of these arguments are defaulted to NIL. In this case, REPRINTENS will be set to those functions that have been changed since the last version of the file was written. For SOURCEFILE, MAKEFILE obtains the full name of the most recent version of the file (that it knows about) from the FILEDATES property of the file, and checks to make sure that the file still exists and has the same file date as that stored on the FILEDATES property. If it does, MAKEFILE uses that file as SOURCEFILE. This procedure permits the user to LOAD or LOADFROM a file in a different directory, and still be able to remake the file with MAKEFILE. In the case where the most recent version of the file cannot be found, MAKEFILE will attempt to remake using the original version of the file (i.e., the one first loaded), specifying as REPRINTENS the union of all changes that have been made since the file was first loaded, which is obtained from the FILECHANGES property of the file. If both of these fail, MAKEFILE prints the message "CAN'T FIND EITHER THE PREVIOUS VERSION OR THE ORIGINAL VERSION OF FILE, SO IT WILL HAVE TO BE WRITTEN ANEW", and does not remake the file, i.e. will prettyprint all of the functions.

When a remake is specified, MAKEFILE also checks to see how the file was originally loaded (see page 17.19). If the file was originally loaded as a compiled file, MAKEFILE will call LOADVARS to obtain those DECLARE: expressions that are contained on the symbolic file, but not the compiled file, and hence have not been loaded. If the file was loaded by LOADFNS (but not LOADFROM), then LOADVARS is called to obtain any non-DEFINEQ expressions. Before calling LOADVARS to re-load definitions, MAKEFILE asks the user, e.g. "Only the compiled version of FOO was loaded, do you want to LOADVARS the DONTCOPY ..) expressions (DECLARE: {DSK}<MYDIR>FOO.;3?". The user can respond Yes to execute the LOADVARS and continue the MAKEFILE, No to proceed with the MAKEFILE without performing the LOADVARS, or Abort to abort the MAKEFILE. The use may wish to skip the LOADVARS if the user had circumvented the file package in some way, and loading the old definitions would overwrite new ones.

Note: Remaking a symbolic file is considerably faster if the earlier version has a *file map* indicating where the function definitions are located (page 17.55), but it does not depend on this information.

# 17.4 Loading Files in a Distributed Environment

Each Interlisp source and compiled code file contains the full filename of the file, including the host and directory names, in a **FILECREATED** expression at the beginning of the file. The compiled code file also contains the full file name of the source file it was created from. In earlier versions of Interlisp, the file package used this information to locate the appropriate source file when "remaking" or recompiling a file.

This turned out to be a bad feature in distributed environments, where users frequently move files from one place to another, or where files are stored on removable media. For example, suppose you MAKEFILE to a floppy, and then copy the file to a file server. If you loaded and edited the file from a file server, and tried to do MAKEFILE, it would try to locate the source file on the floppy, which is probably no longer loaded.

Currently, the file package searches for sources file on the connected directory, and on the directory search path (on the variable **DIRECTORIES**). If it is not found, the host/directory information from the **FILECREATED** expression be used.

Warning: One situation where the new algorithm does the wrong thing is if you explicitly LOADFROM a file that is not on your directory search path. Future MAKEFILEs and CLEANUPs will search the connected directory and DIRECTORIES to find the source file, rather than using the file that the LOADFROM was done from. Even if the correct file is on the directory search path, you could still create a bad file if there is another version of the file in an earlier directory on the search path. In general, you should either explicitly specify the SOURCEFILE argument to MAKEFILE to tell it where to get the old source, or connect to the directory where the correct source file is.

# 17.5 Marking Changes

The file package needs to know what typed definitions have been changed, so it can determine which files need to be updated. This is done by "marking changes". All the system functions that perform file package operations (LOAD, TCOMPL, PRETTYDEF, etc.), as well as those functions that define or change data, (EDITF, EDITV, EDITP, DWIM corrections to user functions) interact with the file package by marking changes. Also, typed-in assignment of variables or property values is noticed by the file package. (Note that if a program modifies a variable or property value, this is not noticed.) In some cases the marking procedure can be subtle, e.g. if the user edits a property list using EDITP, only those properties whose values are actually changed (or added) are marked.

The various system functions which create or modify objects call MARKASCHANGED to mark the object as changed. For example, when a function is defined via DEFINE or DEFINEQ, or modified via EDITF, or a DWIM correction, the function is marked as being a changed object of type FNS. Similarly, whenever a new record is declared, or an existing record redeclared or edited, it is marked as being a changed object of type RECORDS, and so on for all of the other file package types.

The user can also call MARKASCHANGED directly to mark objects of a particular file package type as changed:

#### (MARKASCHANGED NAME TYPE REASON)

[Function]

Marks NAME of type TYPE as being changed.

MARKASCHANGED returns NAME. MARKASCHANGED is undoable.

REASON is a litatom that indicated how NAME was changed. MARKASCHANGED recognizes the following values for REASON:

**DEFINED** Used to indicate the creation of *NAME*, e.g. from **DEFINEQ** (page 10.9).

**CHANGED** Used to indicate a change to *NAME*, e.g. from the editor.

**DELETED** Used to indicate the deletion of *NAME*, e.g. by **DELDEF** (page 17.27).

**CLISP** Used to indicate the modification of *NAME* by CLISP translation.

For backwards compatibility, MARKASCHANGED also accepts a *REASON* of T ( = DEFINED) and NIL ( = CHANGED). New programs should avoid using these values.

Note: The variable MARKASCHANGEDFNS is a list of functions that MARKASCHANGED calls (with arguments NAME, TYPE, and REASON). Functions can be added to this list to "advise" MARKASCHANGED to do additional work for all types of objects. The WHENCHANGED file package type property (page 17.31) can be used to specify additional actions when MARKASCHANGED gets called on specific types of objects.

#### (UNMARKASCHANGED NAME TYPE)

[Function]

Unmarks *NAME* of type *TYPE* as being changed. Returns *NAME* if *NAME* was marked as changed and is now unmarked, **NIL** otherwise. **UNMARKASCHANGED** is undoable.

#### (FILEPKGCHANGES TYPE LST)

[NoSpread Function]

If LST is not specified (as opposed to being NIL), returns a list of those objects of type TYPE that have been marked as changed but not yet associated with their corresponding files (See page 17.21). If LST is specified, FILEPKGCHANGES sets the corresponding list. (FILEPKGCHANGES) returns a list of all objects marked as changed as a list of elements of the form (TYPENAME. CHANGEDOBJECTS).

Some properties (e.g. EXPR, ADVICE, MACRO, I.S.OPR, etc..) are used to implement other file package types. For example, if the user changes the value of the property I.S.OPR, he is really changing an object of type I.S.OPR, and the effect is the same as though he had redefined the i.s.opr via a direct call to the function I.S.OPR. If a property whose value has been changed or added does not correspond to a specific file package type, then it is marked as a changed object of type PROPS whose name is (VARIABLENAME PROPNAME) (except if the property name has a property PROPTYPE with value IGNORE).

Similarly, if the user changes a variable which implements the file package type ALISTS (as indicated by the appearance of the property VARTYPE with value ALIST on the variable's property list), only those entries that are actually changed are marked as being changed objects of type ALISTS, and the "name" of the

object will be (VARIABLENAME KEY) where KEY is CAR of the entry on the alist that is being marked. If the variable corresponds to a specific file package type other than ALISTS, e.g. USERMACROS, LISPXMACROS, etc., then an object of that type is marked. In this case, the name of the changed object will be CAR of the corresponding entry on the alist. For example, if the user edits LISPXMACROS and changes a definition for PL, then the object PL of type LISPXMACROS is marked as being changed.

# 17.6 Noticing Files

Already existing files are "noticed" by LOAD or LOADFROM (or by LOADFNS or LOADVARS when the VARS argument is T. New files are noticed when they are constructed by MAKEFILE, or when definitions are first associated with them via FILES? or ADDTOFILES?. Noticing a file updates certain lists and properties so that the file package functions know to include the file in their operations. For example, CLEANUP will only dump files that have been noticed.

The user can explicitly tell the file package to notice a newly-created file by defining the filecoms for the file (see page 17.32), and calling ADDFILE:

### (ADDFILE *FILE* — — —)

[Function]

Tells the file package that FILE should be recognized as a file; it adds FILE to FILELST, and also sets up the FILE property of FILE to reflect the current set of changes which are "registered against" FILE.

The file package uses information stored on the property list of the root name of noticed files. The following property names are used:

#### **FILE**

[Property Name]

When a file is noticed, the property FILE, value ((FILECOMS . LOADTYPE)) is added to the property list of its root name. FILECOMS is the variable containing the filecoms of the file (see page 17.32). LOADTYPE indicates how the file was loaded, e.g., completely loaded, only partially loaded as with LOADFNS, loaded as a compiled file, etc.

The property FILE is used to determine whether or not the corresponding file has been modified since the last time it was loaded or dumped. CDR of the FILE property records by type

those items that have been changed since the last MAKEFILE. Whenever a file is dumped, these items are moved to the property FILECHANGES, and CDR of the FILE property is reset to NIL. **FILECHANGES** [Property Name] The property FILECHANGES contains a list of all changed items since the file was loaded (there may have been several sequences of editing and rewriting the file). When a file is dumped, the changes in CDR of the FILE property are added to the FILECHANGES property. **FILEDATES** [Property Name] The property FILEDATES contains a list of version numbers and corresponding file dates for this file. These version numbers and dates are used for various integrity checks in connection with remaking a file (see page 17.15). **FILEMAP** [Property Name] The property FILEMAP is used to store the filemap for the file (see page 17.55). This is used to directly load individual functions from the middle of a file. To compute the root name, ROOTFILENAME is applied to the name of the file as indicated in the FILECREATED expression appearing at the front of the file, since this name corresponds to the name the file was originally made under. The file package detects that the file being noticed is a compiled file (regardless of its name), by the appearance of more than one FILECREATED expressions. In this case, each of the files mentioned in the following FILECREATED expressions are noticed. For example, if the user performs (BCOMPL '(FOO FIE)), and subsequently loads FOO.DCOM, both FOO and FIE will be noticed. When a file is noticed, its root name is added to the list FILELST: **FILELST** [Variable] Contains a list of the root names of the files that have been noticed. LOADEDFILEL3 [ [Variable] Contains a list of the actual names of the files as loaded by LOAD, LOADFNS, etc. For example, if the user performs (LOAD '<NEWLISP>EDITA.COM;3), EDITA will be added to FILELST, but <NEWLISP>EDITA.COM;3 is added to LOADEDFILELST. LOADEDFILELST is not used by the file package; it is maintained solely for the user's benefit.

# 17.7 Distributing Change Information

Periodically, the function **UPDATEFILES** is called to find which file(s) contain the elements that have been changed. **UPDATEFILES** is called by **FILES?**, **CLEANUP**, and **MAKEFILES**, i.e., any procedure that requires the **FILE** property to be up to date. This procedure is followed rather than updating the **FILE** property after each change because scanning **FILELST** and examining each file package command can be a time-consuming process; this is not so noticeable when performed in conjunction with a large operation like loading or writing a file.

**UPDATEFILES** operates by scanning **FILELST** and interrogating the file package commands for each file. When (if) any files are found that contain the corresponding typed definition, the name of the element is added to the value of the property FILE Thus, after UPDATEFILES has for the corresponding file. completed operating, the files that need to be dumped are simply those files on FILELST for which CDR of their FILE property is non-NIL. For example, if the user loads the file FOO containing definitions for FOO1, FOO2, and FOO3, edits FOO2, and then calls UPDATEFILES, (GETPROP 'FOO 'FILE) will be ((FOOCOMS . T) (FNS FOO2)). If any objects marked as changed have not been transferred to the FILE property for some file, e.g., the user defines a new function but forgets (or declines) to add it to the file package commands for the corresponding file, then both FILES? and CLEANUP will print warning messages, and then call ADDTOFILES? to permit the user to specify on which files these items belong.

The user can also invoke **UPDATEFILES** directly:

#### (UPDATEFILES — —)

[Function]

(UPDATEFILES) will update the FILE properties of the noticed files.

# 17.8 File Package Types

In addition to the definitions of functions and values of variables, source files in Interlisp can contain a variety of other information, e.g. property lists, record declarations, macro definitions, hash arrays, etc. In order to treat such a diverse assortment of data uniformly from the standpoint of file operations, the file package uses the concept of a typed definition, of which a function definition is just one example. A typed definition associates with a name (usually a litatom), a definition of a given type (called the file package type). Note

that the same name may have several definitions of different types. For example, a litatom may have both a function definition and a variable definition. The file package also keeps track of the file that a particular typed definition is stored on, so one can think of a typed definition as a relation between four elements: a name, a definition, a type, and a file.

A file package type is an abstract notion of a class of objects which share the property that every object of the same file package type is stored, retrieved, edited, copied etc., by the file package in the same way. Each file package type is identified by a litatom, which can be given as an argument to the functions that manipulate typed definitions. The user may define new file package types, as described in page 17.32.

#### **FILEPKGTYPES**

[Variable]

The value of FILEPKGTYPES is a list of all file package types, including any that may have been defined by the user.

The file package is initialized with the following built-in file package types:

#### **ADVICE**

[File Package Type]

Used to access "advice" modifying a function (see page 15.9).

#### **ALISTS**

[File Package Type]

Used to access objects stored on an association list that is the value of a litatom (see page 3.15).

A variable is declared to have an association list as its value by putting on its property list the property VARTYPE with value ALIST. In this case, each dotted pair on the list is an object of type ALISTS. When the value of such a variable is changed, only those entries in the association list that are actually changed or added are marked as changed objects of type ALISTS (with "name" (LITATOM KEY)). Objects of type ALISTS are dumped via the ALISTS or ADDVARS file package commands.

Note that some association lists are used to "implement" other file package types. For example, the value of the global variable USERMACROS implements the file package type USERMACROS and the values of LISPXMACROS and LISPXHISTORYMACROS implement the file package type LISPXMACROS. This is indicated by putting on the property list of the variable the property VARTYPE with value a list of the form (ALIST FILEPKGTYPE). For example, (GETPROP 'LISPXHISTORYMACROS 'VARTYPE) => (ALIST LISPXMACROS).

COURIERPROGRAMS	[File Package Type]
	Used to access Courier programs (see page 31.15).
EVENESCIONIS	ten a la tra
EXPRESSIONS	[File Package Type] Used to access lisp expressions that are put on a file by using the
	REMEMBER programmers assistant command (page 13.17), or by
	explicitly putting the P file package command (page 17.40) on
	the filecoms.
FIELDS	[File Package Type]
	Used to access fields of records. The "definition" of an object of
	type <b>FIELDS</b> is a list of all the record declarations which contain the name. See page 8.1.
FILEPKGCOMS	[File Package Type]
	Used to access file package commands and types. A single name
	can be defined both as a file package type and a file package
	command. The "definition" of an object of type FILEPKGCOMS
	is a list structure of the form ((COM . COMPROPS) (TYPE . TYPEPROPS)), where COMPROPS is a property list specifying how
	the name is defined as a file package command by FILEPKGCOM
	(page 17.47), and <i>TYPEPROPS</i> is a property list specifying how
	the name is defined as a file package type by FILEPKGTYPE (page 17.32).
FILES	[File Package Type]
	Used to access files. This file package type is most useful for
	renaming files. The "definition" of a file is not a useful structure.
FILEVARS	[File Package Type]
	Used to access Filevars (see page 17.44).
FNS	[File Package Type]
	Used to access function definitions.
1.S.OPRS	[File Package Type]
	Used to access the definitions of iterative statement operators (see page 9.9).
LISPXMACROS	[File Package Type]
	Used to access programmer's assistant commands defined on the variables LISPXMACROS and LISPXHISTORYMACROS (see page 13.23).

MACROS	[File Package Type]
	Used to access macro definitions (see page 10.21).
PROPS	[File Package Type]
	Used to access objects stored on the property list of a litatom (see page 2.5). When a property is changed or added, an object of type PROPS, with "name" (LITATOM PROPNAME) is marked as being changed.
	Note that some litatom properties are used to implement other file package types. For example, the property MACRO implements the file package type MACROS, the property ADVICE implements ADVICE, etc. This is indicated by putting the property PROPTYPE, with value of the file package type on the property list of the property name. For example, (GETPROP 'MACRO 'PROPTYPE) => MACROS. When such a property is changed or added, an object of the corresponding file package type is marked. If (GETPROP PROPNAME 'PROPTYPE) => IGNORE, the change is ignored. The FILE, FILEMAP, FILEDATES,
	etc. properties are all handled this way. (Note that <b>IGNORE</b> cannot be the name of a file package type implemented as a property).
RECORDS	cannot be the name of a file package type implemented as a
RECORDS	cannot be the name of a file package type implemented as a property).
RECORDS RESOURCES	cannot be the name of a file package type implemented as a property).  [File Package Type]  Used to access record declarations (see page 8.1).  [File Package Type]
	cannot be the name of a file package type implemented as a property).  [File Package Type]  Used to access record declarations (see page 8.1).
	cannot be the name of a file package type implemented as a property).  [File Package Type]  Used to access record declarations (see page 8.1).  [File Package Type]
RESOURCES	cannot be the name of a file package type implemented as a property).  [File Package Type]  Used to access record declarations (see page 8.1).  [File Package Type]  Used to access resources (see page 12.19).
RESOURCES	cannot be the name of a file package type implemented as a property).  [File Package Type]  Used to access record declarations (see page 8.1).  [File Package Type]  Used to access resources (see page 12.19).  [File Package Type]  Used to access Masterscope templates (see page 19.18).  [File Package Type]
RESOURCES TEMPLATES	cannot be the name of a file package type implemented as a property).  [File Package Type]  Used to access record declarations (see page 8.1).  [File Package Type]  Used to access resources (see page 12.19).  [File Package Type]  Used to access Masterscope templates (see page 19.18).
RESOURCES TEMPLATES	cannot be the name of a file package type implemented as a property).  [File Package Type]  Used to access record declarations (see page 8.1).  [File Package Type]  Used to access resources (see page 12.19).  [File Package Type]  Used to access Masterscope templates (see page 19.18).  [File Package Type]

# 17.8.1 Functions for Manipulating Typed Definitions

The functions described below can be used to manipulate typed definitions, without needing to know how the manipulations are done. For example, (GETDEF 'FOO 'FNS) will return the function definition of FOO, (GETDEF 'FOO 'VARS) will return the variable value of FOO, etc. All of the functions use the following conventions:

- (1) All functions which make destructive changes are undoable.
- (2) Any argument that expects a list of litatoms will also accept a single litatom, operating as though it were enclosed in a list. For example, if the argument *FILES* should be a list of files, it may also be a single file.
- (3) TYPE is a file package type. TYPE = NIL is equivalent to TYPE = FNS. The singular form of a file package type is also recognized, e.g. TYPE = VAR is equivalent to TYPE = VARS.
- (4) FILES = NIL is equivalent to FILES = FILELST.
- (5) **SOURCE** is used to indicate the source of a definition, that is, where the definition should be found. **SOURCE** can be one of:

#### **CURRENT**

Get the definition currently in effect.

SAVED

Get the "saved" definition, as stored by SAVEDEF (page 17.27).

FILE

Get the definition contained on the (first) file determined by WHEREIS (page 17.14).

Note: WHEREIS is called with FILES = T, so that if the WHEREIS library package is loaded, the WHEREIS data base will be used to find the file containing the definition.

? Get the definition currently in effect if there is one, else the saved definition if there is one, otherwise the definition from a file determined by WHEREIS. Like specifying CURRENT, SAVED, and FILE in order, and taking the first definition that is found.

# a file name a list of file names

Get the definition from the first of the indicated files that contains one.

NIL

In most cases, giving SOURCE = NIL (or not specifying it at all) is the same as giving ?, to get either the current, saved, or filed definition. However, with HASDEF, SOURCE = NIL is interpreted as equal to SOURCE = CURRENT, which only tests if there is a current definition.

The operation of most of the functions described below can be changed or extended by modifying the appropriate properties for the corresponding file package type using the function **FILEPKGTYPE**, described on page 17.32.

#### (GETDEF NAME TYPE SOURCE OPTIONS)

[Function]

Returns the definition of *NAME*, of type *TYPE*, from *SOURCE*. For most types, **GETDEF** returns the expression which would be pretty printed when dumping *NAME* as *TYPE*. For example, for *TYPE* = **FNS**, an **EXPR** definition is returned, for *TYPE* = **VARS**, the value of *NAME* is returned, etc.

**OPTIONS** is a list which specifies certain options:

**NOERROR** 

**GETDEF** causes an error if an appropriate definition cannot be found, unless *OPTIONS* is or contains **NOERROR**. In this case,

**GETDEF** returns the value of the **NULLDEF** file package type property (page 17.30), usually **NIL**.

a string

If *OPTIONS* is or contains a string, that string will be returned if no definition is found (and **NOERROR** is not among the options). The caller can thus determine whether a definition was found, even for types for which **NIL** or **NOBIND** are acceptable definitions.

NOCOPY

**GETDEF** returns a copy of the definition unless *OPTIONS* is or contains **NOCOPY**.

**EDIT** 

If *OPTIONS* is or contains **EDIT**, **GETDEF** returns a copy of the definition unless it is possible to edit the definition "in place." With some file package types, such as functions, it is meaningful (and efficient) to edit the definition by destructively modifying the list structure, without calling **PUTDEF**. However, some file package types (like records) need to be "installed" with **PUTDEF** after they are edited. The default **EDITDEF** (see page 17.31) calls **GETDEF** with *OPTIONS* of **(EDIT NOCOPY)**, so it doesn't use a copy unless it has to, and only calls **PUTDEF** if the result of editing is not **EQUAL** to the old definition.

**NODWIM** 

A FNS definition will be dwimified if it is likely to contain CLISP unless OPTIONS is or contains NODWIM.

### (PUTDEF NAME TYPE DEFINITION REASON)

[Function]

Defines *NAME* of type *TYPE* with *DEFINITION*. For *TYPE* = FNS, does a **DEFINE**; for *TYPE* = VARS, does a SAVESET, etc.

For TYPE = FILES, PUTDEF establishes the command list, notices NAME, and then calls MAKEFILE to actually dump the file NAME, copying functions if necessary from the "old" file (supplied as part of DEFINITION).

**PUTDEF** calls **MARKASCHANGED** (page 17.17) to mark *NAME* as changed, giving a reason of *REASON*. If *REASON* is **NIL**, the default is **DEFINED**.

Note: If TYPE = FNS, PUTDEF prints a warning if the user tries to redefine a function on the list UNSAFE.TO.MODIFY.FNS (page 10.10).

### (HASDEF NAME TYPE SOURCE SPELLFLG)

[Function]

Returns (**OR** *NAME* **T**) if *NAME* is the name of something of type *TYPE*. If not, attempts spelling correction if *SPELLFLG* = **T**, and returns the spelling-corrected *NAME*. Otherwise returns **NIL**.

(HASDEF NIL TYPE) returns T if NIL has a valid definition.

Note: if SOURCE = NIL, HASDEF interprets this as equal to SOURCE = CURRENT, which only tests if there is a current definition.

#### (TYPESOF NAME POSSIBLETYPES IMPOSSIBLETYPES SOURCE)

[Function]

Returns a list of the types in *POSSIBLETYPES* but not in *IMPOSSIBLETYPES* for which *NAME* has a definition. **FILEPKGTYPES** is used if *POSSIBLETYPES* is **NIL**.

### (COPYDEF OLD NEW TYPE SOURCE OPTIONS)

[Function]

Defines *NEW* to have a copy of the definition of *OLD* by doing **PUTDEF** on a copy of the definition retrieved by **(GETDEF** *OLD TYPE SOURCE OPTIONS)*. *NEW* is substituted for *OLD* in the copied definition, in a manner that may depend on the *TYPE*.

For example, (COPYDEF 'PDQ 'RST 'FILES) sets up RSTCOMS to be a copy of PDQCOMS, changes things like (VARS \* PDQVARS) to be (VARS \* RSTVARS) in RSTCOMS, and performs a MAKEFILE on RST such that the appropriate definitions get copied from PDQ.

**COPYDEF** disables the **NOCOPY** option of **GETDEF**, so *NEW* will always have a *copy* of the definition of *OLD*.

Note: **COPYDEF** substitutes *NEW* for *OLD* throughout the definition of *OLD*. This is usually the right thing to do, but in some cases, e.g., where the old name appears within a quoted expression but was not used in the same context, the user must re-edit the definition.

### (DELDEF NAME TYPE)

[Function]

Removes the definition of *NAME* as a *TYPE* that is currently in effect.

#### (SHOWDEF NAME TYPE FILE)

[Function]

Prettyprints the definition of NAME as a TYPE to FILE. This shows the user how NAME would be written to a file. Used by ADDTOFILES? (page 17.13).

### (EDITDEF NAME TYPE SOURCE EDITCOMS)

[Function]

Edits the definition of NAME as a TYPE. Essentially performs

(PUTDEF NAME TYPE

(EDITE (GETDEF NAME TYPE SOURCE)

EDITCOMS))

#### (SAVEDEF NAME TYPE DEFINITION)

[Function]

Sets the "saved" definition of NAME as a TYPE to DEFINITION. If DEFINITION = NIL, the current definition of NAME is saved.

If TYPE = FNS (or NIL), the function definition is saved on NAME's property list under the property EXPR, or CODE (depending on the FNTYP of the function definition). If (GETD NAME) is non-NIL, but (FNTYP FN) = NIL, SAVEDEF saves the definition on the property name LIST. This can happen if a function was

somehow defined with an illegal expr definition, such as (LAMMMMDA (X) ...).

If TYPE = VARS, the definition is stored as the value of the VALUE property of NAME. For other types, the definition is stored in an internal data structure, from where it can be retrieved by GETDEF or UNSAVEDEF.

### (UNSAVEDEF NAME TYPE ---)

[Function]

Restores the "saved" definition of *NAME* as a *TYPE*, making it be the current definition. Returns *PROP*.

If TYPE = FNS (or NIL), UNSAVEDEF unsaves the function definition from the EXPR property if any, else CODE, and returns the property name used. UNSAVEDEF also recognizes TYPE = EXPR, CODE, or LIST, meaning to unsave the definition only from the corresponding property only.

If **DFNFLG** is not **T** (see page 10.10), the current definition of *NAME*, if any, is saved using **SAVEDEF**. Thus one can use **UNSAVEDEF** to switch back and forth between two definitions.

#### (LOADDEF NAME TYPE SOURCE)

[Function]

Equivalent to (PUTDEF NAME TYPE (GETDEF NAME TYPE SOURCE)). LOADDEF is essentially a generalization of LOADFNS, e.g. it enables loading a single record declaration from a file. Note that (LOADDEF FN) will give FN an EXPR definition, either obtained from its property list or a file, unless it already has one.

#### (CHANGECALLERS OLD NEW TYPES FILES METHOD)

[Function]

Finds all of the places where *OLD* is used as any of the types in *TYPES* and changes those places to use *NEW*. For example, **(CHANGECALLERS 'NLSETQ 'ERSETQ)** will change all calls to **NLSETQ** to be calls to **ERSETQ**. Also changes occurrences of *OLD* to *NEW* inside the filecoms of any file, inside record declarations, properties, etc.

CHANGECALLERS attempts to determine if *OLD* might be used as more than one type; for example, if it is both a function and a record field. If so, rather than performing the transformation *OLD -> NEW* automatically, the user is allowed to edit all of the places where *OLD* occurs. For each occurrence of *OLD*, the user is asked whether he wants to make the replacement. If he responds with anything except **Yes** or **No**, the editor is invoked on the expression containing that occurrence.

There are two different methods for determining which functions are to be examined. If METHOD = EDITCALLERS, EDITCALLERS is used to search FILES (see page 16.74). If METHOD = MASTERSCOPE, then the Masterscope database is used instead. METHOD = NIL defaults to MASTERSCOPE if the

value of the variable **DEFAULTRENAMEMETHOD** is **MASTERSCOPE** and a Masterscope database exists, otherwise it defaults to **EDITCALLERS**.

### (RENAME OLD NEW TYPES FILES METHOD)

[Function]

First performs (COPYDEF OLD NEW TYPE) for all TYPE inside TYPES. It then calls CHANGECALLERS to change all occurrences of OLD to NEW, and then "deletes" OLD with DELDEF. For example, if the user has a function FOO which he now wishes to call FIE, he simply performs (RENAME 'FOO 'FIE), and FIE will be given FOO's definition, and all places that FOO are called will be changed to call FIE instead.

**METHOD** is interpreted the same as the **METHOD** argument to **CHANGECALLERS**, above.

#### (COMPARE NAME1 NAME2 TYPE SOURCE1 SOURCE2)

[Function]

Compares the definition of *NAME1* with that of *NAME2*, by calling **COMPARELISTS** (page 3.19) on **(GETDEF** *NAME1 TYPE SOURCE1*) and **(GETDEF** *NAME2 TYPE SOURCE2*), which prints their differences on the terminal.

For example, if the current value of the variable A is (A B C (D E F) G), and the value of the variable B on the file < lisp>FOO is (A B C (D F E) G), then:

←(COMPARE 'A 'B 'VARS 'CURRENT' < lisp>FOO)
A from CURRENT and B from < lisp>TEST differ:
(E-> F) (F-> E)
T

#### (COMPAREDEFS NAME TYPE SOURCES)

[Function]

Calls COMPARELISTS (page 3.19) on all pairs of definitions of *NAME* as a *TYPE* obtained from the various *SOURCES* (interpreted as a list of source specifications).

# 17.8.2 Defining New File Package Types

All manipulation of typed definitions in the file package is done using the type-independent functions **GETDEF**, **PUTDEF**, etc. Therefore, to define a new file package type, it is only necessary to specify (via the function **FILEPKGTYPE**) what these functions should do when dealing with a typed definition of the new type. Each file package type has the following properties, whose values are functions or lists of functions:

Note: These functions are defined to take a *TYPE* argument so that the user may have the same function for more than one type.

GETDEF	[File Package Type Property]
	Value is a function of three arguments, NAME, TYPE, and OPTIONS, which should return the current definition of NAME as a type TYPE. Used by GETDEF (page 17.25), which passes its OPTIONS argument.
	If there is no <b>GETDEF</b> property, a file package command for dumping <i>NAME</i> is created (by <b>MAKENEWCOM</b> ). This command is then used to write the definition of <i>NAME</i> as a type <i>TYPE</i> onto the file <b>FILEPKG.SCRATCH</b> (in Interlisp-D, this file is created on the <b>{CORE}</b> device). This expression is then read back in and returned as the current definition.
	Note: In some situations, the function HASDEF (page 17.26) needs to call GETDEF to determine whether a definition exists. In this case, OPTIONS will include the litatom HASDEF, and it is permissable for a GETDEF function to return T or NIL, rather than creating a complex structure which will not be used.
NULLDEF	[File Package Type Property]
	The value of the <b>NULLDEF</b> property is returned by <b>GETDEF</b> (page 17.25) when there is no definition and the <b>NOERROR</b> option is supplied. For example, the <b>NULLDEF</b> of <b>VARS</b> is <b>NOBIND</b> .
FILEGETDEF	[File Package Type Property]
	This enables the user to provide a way of obtaining definitions from a file that is more efficient than the default procedure used by GETDEF (page 17.25). Value is a function of four arguments, NAME, TYPE, FILE, and OPTIONS. The function is applied by GETDEF when it is determined that a typed definition is needed from a particular file. The function must open and search the given file and return any TYPE definition for NAME that it finds.
CANFILEDEF	[File Package Type Property]
	If the value of this property is non-NIL, this indicates that definitions of this file package type are not loaded when a file is loaded with LOADFROM (page 17.8). The default is NIL. Initially, only FNS has this property set to non-NIL.
PUTDEF	[File Package Type Property]
	Value is a function of three arguments, NAME, TYPE, and DEFINITION, which should such DEFINITION as the definition of NAME as a type TYPE. Used by PUTDEF (page 17.26).
HASDEF	[File Package Type Property]
	Value is a function of three arguments, NAME, TYPE, and SOURCE, which should return (OR NAME T) if NAME is the name

of something of type *TYPE*. *SOURCE* is as interpreted by **HASDEF** (page 17.26), which uses this property.

#### **EDITDEF**

#### [File Package Type Property]

Value is a function of four arguments, NAME, TYPE, SOURCE, and EDITCOMS, which should edit the definition of NAME as a type TYPE from the source SOURCE, interpreting the edit commands EDITCOMS. If sucessful, should return NAME (or a spelling-corrected NAME). If it returns NIL, the "default" editor is called. Used by EDITDEF (page 17.27).

#### **DELDEF**

## [File Package Type Property]

Value is a function of two arguments, *NAME*, and *TYPE*, which removes the definition of *NAME* as a *TYPE* that is currently in effect. Used by **DELDEF** (page 17.27).

#### **NEWCOM**

### [File Package Type Property]

Value is a function of four arguments, NAME, TYPE, LISTNAME, and FILE. Specifies how to make a new (instance of a) file package command to dump NAME, an object of type TYPE. The function should return the new file package command. Used by ADDTOFILE and SHOWDEF.

If LISTNAME is non-NIL, this means that the user specified LISTNAME as the filevar in his interaction with ADDTOFILES? (see page 17.44).

If no **NEWCOM** is specified, the default is to call **DEFAULTMAKENEWCOM**, which will construct and return a command of the form (*TYPE NAME*). **DEFAULTMAKENEWCOM** can be advised or redefined by the user.

#### WHENCHANGED

#### [File Package Type Property]

Value is a list of functions to be applied to NAME, TYPE, and REASON when NAME, an instance of type TYPE, is changed or defined (see MARKASCHANGED, page 17.17). Used for various applications, e.g. when an object of type I.S.OPRS changes, it is necessary to clear the corresponding translatons from CLISPARRAY.

The WHENCHANGED functions are called before the object is marked as changed, so that it can, in fact, decide that the object is *not* to be marked as changed, and execute (RETFROM 'MARKASCHANGED).

Note: For backwards compatibility, the *REASON* argument passed to **WHENCHANGED** functions is either **T** (for **DEFINED**) and **NIL** (for **CHANGED**).

WHENFILED	(File Package Type Prop	erty]
	Value is a list of functions to be applied to NAME, TYPE, and	1 FILE
	when NAME, an instance of type TYPE, is added to FILE.	
		_
WHENUNFILED	[File Package Type Prop	
	Value is a list of functions to be applied to NAME, TYPE, and	
	when NAME, an instance of type TYPE, is removed from FILE	<u> </u>
DESCRIPTION	[File Package Type Prop	erty]
	Value is a string which describes instances of this type. example, for type RECORDS, the value of DESCRIPTION is string "record declarations".	
	The function <b>FILEPKGTYPE</b> is used to define new file pactypes, or to change the properties of existing types. Note this possible to redefine the attributes of system file package to such as <b>FNS</b> or <b>PROPS</b> .	hat it
(FILEPKGTYPE TYPE P	POP <sub>1</sub> VAL <sub>1</sub> PROP <sub>N</sub> VAL <sub>N</sub> ) [NoSpread Fund	tion]
	Nospread function for defining new file package type changing properties of existing file package types. <i>PROP</i> <sub>i</sub> is of the property names given above; <i>VAL</i> <sub>i</sub> is the value to be to that property. Returns <i>TYPE</i> .	s one
	(FILEPKGTYPE TYPE PROP) returns the value of the property PROP, without changing it.	perty
	(FILEPKGTYPE TYPE) returns an alist of all of the determination properties of TYPE, using the property names as keys.	fined
	Note: Specifying TYPE as the litatom TYPE can be used to do one file package type as a synonym of another. For exam (FILEPKGTYPE 'R 'TYPE 'RECORDS) defines R as a synonym for file package type RECORDS.	nple,

# 17.9 File Package Commands

The basic mechanism for creating symbolic files is the function MAKEFILE (page 17.10). For each file, the file package has a data structure known as the "filecoms", which specifies what typed descriptions are contained in the file. A filecoms is a list of file package commands, each of which specifies objects of a certain file package type which should be dumped. For example, the filecoms

( (FNS FOO) (VARS FOO BAR BAZ)

# (RECORDS XYZZY) )

has a FNS, a VARS, and a RECORDS file package command. This filecoms specifies that the function definition for FOO, the variable values of FOO, BAR, and BAZ, and the record declaration for XYZZY should be dumped.

By convention, the filecoms of a file X is stored as the value of the litatom XCOMS. For example, (MAKEFILE 'FOO.;27) will use the value of FOOCOMS as the filecoms. This variable can be directly manipulated, but the file package contains facilities which make constructing and updating filecoms easier, and in some cases automatic (See page 17.48).

A file package command is an instruction to MAKEFILE to perform an explicit, well-defined operation, usually printing an Usually there is a one-to-one correspondence expression. between file package types and file package commands; for each file package type, there is a file package command which is used for writing objects of that type to a file, and each file package command is used to write objects of a particular type. However, in some cases, the same file package type can be dumped by several different file package commands. example, the file package commands PROP, IFPROP, and PROPS all dump out objects with the file package type PROPS. This means if the user changes an object of file package type PROPS via EDITP, a typed-in call to PUTPROP, or via an explicit call to MARKASCHANGED, this object can be written out with any of the above three commands. Thus, when the file package attempts to determine whether this typed object is contained on • a particular file, it must look at instances of all three file package commands PROP, IFPROP, and PROPS, to see if the corresponding atom and property are specified. It is also permissible for a single file package command to dump several different file package types. For example, the user can define a file package command which dumps both a function definition and its macro. Conversely, some file package comands do not dump any file

For each file package command, the file package must be able to determine what typed definitions the command will cause to be printed so that the file package can determine on what file (if any) an object of a given type is contained (by searching through the filecoms). Similarly, for each file package type, the file package must be able to construct a command that will print out an object of that type. In other words, the file package must be able to map file package commands into file package types, and vice versa. Information can be provided to the file package about a particular file package command via the function FILEPKGCOM (page 17.47), and information about a particular file package type via the function FILEPKGTYPE (page 17.32). In the absence of other information, the default is simply that a file

package types at all, such as the E command.

package command of the form (X NAME) prints out the definition of NAME as a type X, and, conversely, if NAME is an object of type X, then NAME can be written out by a command of the form (X NAME).

If a file package function is given a command or type that is not defined, it attempts spelling correction using FILEPKGCOMSPLST as a spelling list (unless DWIMFLG or NOSPELLFLG = NIL; see page 20.13). If successful, the corrected version of the list of file package commands is written (again) on the output file, since at this point, the uncorrected list of file package commands would already have been printed on the output file. When the file is loaded, this will result in FILECOMS being reset, and may cause a message to be printed, e.g., (FOOCOMS RESET). The value of FOOCOMS would then be the corrected version. If the spelling correction is unsuccessful, the file package functions generate an error, BAD FILE PACKAGE COMMAND.

File package commands can be used to save on the output file definitions of functions, values of variables, property lists of atoms, advised functions, edit macros, record declarations, etc. The interpretation of each file package command is documented in the following sections.

### (USERMACROS LITATOM<sub>1</sub> ... LITATOM<sub>N</sub>)

[File Package Command]

Each litatom  $LITATOM_i$  is the name of a user edit macro. Writes expressions to add the edit macro definitions of  $LITATOM_i$  to USERMACROS, and adds the names of the commands to the appropriate spelling lists.

If  $LITATOM_i$  is not a user macro, a warning message "no EDIT MACRO for  $LITATOM_i$ " is printed.

#### 17.9.1 Functions and Macros

# (FNS FN<sub>1</sub> ... FN<sub>N</sub>)

[File Package Command]

Writes a **DEFINEQ** expression with the function definitions of  $FN_1$  ...  $FN_N$ .

The user should never print a **DEFINEQ** expression directly onto a file himself (by using the **P** file package command, for example), because **MAKEFILE** generates the filemap of function definitions from the **FNS** file package commands (see page 17.55).

# (ADVISE *FN*<sub>1</sub> ... *FN*<sub>N</sub>)

[File Package Command]

For each function  $FN_i$ , writes expressions to reinstate the function to its advised state when the file is loaded. See page 15.9.

Note: When advice is applied to a function programmatically or by hand, it is additive. That is, if a function already has some advice, further advice is added to the already-existing advice. However, when advice is applied to a function as a result of loading a file with an ADVISE file package command, the new advice replaces any earlier advice. ADVISE works this way to prevent problems with loading different versions of the same advice. If the user really wants to apply additive advice, a file package command such as (P (ADVISE ...)) should be used (see page 17.40).

#### (ADVICE FN<sub>1</sub> ... FN<sub>N</sub>)

[File Package Command]

For each function  $FN_i$ , writes a PUTPROPS expression which will put the advice back on the property list of the function. The user can then use READVISE (page 15.12) to reactivate the advice.

#### (MACROS LITATOM<sub>1</sub> ... LITATOM<sub>N</sub>)

[File Package Command]

Each LITATOM<sub>i</sub> is a litatom with a MACRO definition (and/or a DMACRO, 10MACRO, etc.). Writes out an expression to restore all of the macro properties for each LITATOM<sub>i</sub>, embedded in a DECLARE: EVAL@COMPILE so the macros will be defined when the file is compiled. See page 10.21.

#### 17.9.2 Variables

# (VARS VAR<sub>1</sub> ... VAR<sub>N</sub>)

[File Package Command]

For each  $VAR_i$ , writes an expression to set its top level value when the file is loaded. If  $VAR_i$  is atomic, VARS writes out an expression to set  $VAR_i$  to the top-level value it had at the time the file was written. If  $VAR_i$  is non-atomic, it is interpreted as  $(VAR\ FORM)$ , and VARS write out an expression to set VAR to the value of FORM (evaluated when the file is loaded).

VARS prints out expressions using RPAQQ and RPAQ, which are like SETQQ and SETQ except that they also perform some special operations with respect to the file package (see page 17.54).

Note: VARS cannot be used for putting arbitrary variable values on files. For example, if the value of a variable is an array (or many other data types), a litatom which expresents the array is dumped in the file instead of the array itself. The HORRIBLEVARS file package command (page 17.36) provides a way of saving and reloading variables whose values contain re-entrant or circular list structure, user data types, arrays, or hash arrays.

# (INITVARS VAR1 ... VARN)

[File Package Command]

INITVARS is used for initializing variables, setting their values only when they are currently NOBIND. A variable value defined in an INITVARS command will not change an already established value. This means that re-loading files to get some other information will not automatically revert to the initialization values.

The format of an INITVARS command is just like VARS. The only difference is that if  $VAR_i$  is atomic, the current value is not dumped; instead NIL is defined as the initialization value. Therefore, (INITVARS FOO (FUM 2)) is the same as (VARS (FOO NIL)(FUM 2)), if FOO and FUM are both NOBIND.

**INITVARS** writes out an RPAQ? expression on the file instead of RPAQ or RPAQQ.

# $(ADDVARS(VAR_1.LST_1)...(VAR_N.LST_N))$

[File Package Command]

For each  $(VAR_i . LST_i)$ , writes an ADDTOVAR (page 17.54) to add each element of  $LST_i$  to the list that is the value of  $VAR_i$  at the time the file is loaded. The new value of  $VAR_i$  will be the union of its old value and  $LST_i$ . If the value of  $VAR_i$  is **NOBIND**, it is first set to **NIL**.

For example, (ADDVARS (DIRECTORIES LISP LISPUSERS)) will add LISP and LISPUSERS to the value of DIRECTORIES.

If  $LST_i$  is not specified,  $VAR_i$  is initialized to NIL if its current value is **NOBIND**. In other words, (ADDVARS (VAR)) will initialize VAR to NIL if VAR has not previously been set.

#### (APPENDVARS ( $VAR_1 . LST_1$ ) ... ( $VAR_N . LST_N$ ))

[File Package Command]

The same as ADDVARS, except that the values are added to the end of the lists (using APPENDTOVAR, page 17.55), rather than at the beginning.

# (UGLYVARS VAR1 ... VARN)

[File Package Command]

Like VARS, except that the value of each VAR<sub>i</sub> may contain structures for which READ is not an inverse of PRINT, e.g. arrays, readtables, user data types, etc. Uses HPRINT (page 25.17).

# (HORRIBLEVARS VAR; .. VARN)

[File Package Command]

Like **UGLYVARS**, except structures may also contain circular pointers. Uses **HPRINT** (page 25.17). The values of  $VAR_1 \dots VAR_N$  are printed in the same operation, so that they may contain pointers to common substructures.

UGLYVARS does not do any checking for circularities, which results in a large speed and internal-storage advantage over

**HORRIBLEVARS**. Thus, if it is known that the data structures do *not* contain circular pointers, **UGLYVARS** should be used instead of **HORRIBLEVARS**.

# (ALISTS ( $VAR_1 KEY_1 KEY_2 ...$ ) ... ( $VAR_N KEY_3 KEY_4 ...$ ))

[File Package Command]

VAR<sub>i</sub> is a variable whose value is an association list, such as EDITMACROS, BAKTRACELST, etc. For each VAR<sub>i</sub>, ALISTS writes out expressions which will restore the values associated with the specified keys. For example, (ALISTS (BREAKMACROS BT BTV)) will dump the definition for the BT and BTV commands on BREAKMACROS.

Some association lists (USERMACROS, LISPXMACROS, etc.) are used to implement other file package types, and they have their own file package commands.

(SPECVARS VAR<sub>1</sub> ... VAR<sub>N</sub>)

[File Package Command]

(LOCALVARS VAR<sub>1</sub> ... VAR<sub>N</sub>)

[File Package Command]

(GLOBALVARS VAR<sub>1</sub> ... VAR<sub>N</sub>)

[File Package Command]

Outputs the corresponding compiler declaration embedded in a **DECLARE: DOEVAL@COMPILE DONTCOPY**. See page 18.5.

(CONSTANTS VAR<sub>1</sub> ... VAR<sub>N</sub>)

[File Package Command]

Like VARS, for each VAR; writes an expression to set its top level value when the file is loaded. Also writes a CONSTANTS expression to declare these variables as constants (see page 18.8). Both of these expressions are wrapped in a (DECLARE: EVAL@COMPILE ...) expression, so they can be used by the compiler.

Like VARS,  $VAR_i$  can be non-atomic, in which case it is interpreted as ( $VAR\ FORM$ ), and passed to CONSTANTS (along with the variable being initialized to FORM).

#### 17.9.3 Litatom Properties

# (PROP PROPNAME LITATOM $_1$ ... LITATOM $_N$ )

[File Package Command]

Writes a **PUTPROPS** expression to restore the value of the *PROPNAME* property of each litatom *LITATOM*; when the file is loaded.

If PROPNAME is a list, expressions will be written for each property on that list. If PROPNAME is the litatom ALL, the values of all user properties (on the property list of each  $LITATOM_i$ ) are

saved. **SYSPROPS** is a list of properties used by system functions. Only properties *not* on that list are dumped when the ALL option is used.

If LITATOM; does not have the property PROPNAME (as opposed to having the property with value NIL), a warning message "NO PROPNAME PROPERTY FOR LITATOM;" is printed. The command IFPROP can be used if it is not known whether or not an atom will have the corresponding property.

# (IFPROP PROPNAME LITATOM<sub>1</sub> ... LITATOM<sub>N</sub>)

[File Package Command]

Same as the PROP file package command, except that it only saves the properties that actually appear on the property list of the corresponding atom. For example, if FOO1 has property PROP1 and PROP2, FOO2 has PROP3, and FOO3 has property PROP1 and PROP3, then (IFPROP (PROP1 PROP2 PROP3) FOO1 FOO2 FOO3) will save only those five property values.

#### (PROPS (LITATOM<sub>1</sub> PROPNAME<sub>1</sub>) ... (LITATOM<sub>N</sub> PROPNAME<sub>N</sub>)) [File Package Command]

Similar to **PROP** command. Writes a **PUTPROPS** expression to restore the value of  $PROPNAME_i$  for each  $LITATOM_i$  when the file is loaded.

As with the **PROP** command, if  $LITATOM_i$  does not have the property PROPNAME (as opposed to having the property with **NIL** value), a warning message "**NO**  $PROPNAME_i$  **PROPERTY FOR**  $LITATOM_i$ " is printed.

# 17.9.4 Miscellaneous File Package Commands

#### (RECORDS $REC_1 \dots REC_N$ )

[File Package Command]

Each  $REC_i$  is the name of a record (see page 8.1). Writes expressions which will redeclare the records when the file is loaded.

#### (INITRECORDS REC<sub>1</sub> ... REC<sub>N</sub>)

[File Package Command]

Similar to **RECORDS**, **INITRECORDS** writes expressions on a file that will, when loaded, perform whatever initialization/allocation is necessary for the indicated records. However, the record declarations themselves are not written out. This facility is useful for building systems on top of Interlisp, in which the implementor may want to eliminate the record declarations from a production version of the system, but the allocation for these records must still be done.

#### (LISPXMACROS LITATOM<sub>1</sub> ... LITATOM<sub>N</sub>)

[File Package Command]

Each  $LITATOM_i$  is defined on LISPXMACROS or LISPXHISTORYMACROS (see page 13.23). Writes expressions which will save and restore the definition for each macro, as well as making the necessary additions to LISPXCOMS

#### (I.S.OPRS OPR<sub>1</sub> ... OPR<sub>N</sub>)

[File Package Command]

Each  $OPR_i$  is the name of a user-defined i.s.opr (see page 9.20). Writes expressions which will redefine the i.s.oprs when the file is loaded.

#### (RESOURCES RESOURCE 1 ... RESOURCE N)

[File Package Command]

Each  $RESOURCES_i$  is the name of a resource (see page 12.19). Writes expressions which will redeclare the resource when the file is loaded.

### (INITRESOURCES RESOURCE 1 ... RESOURCE N)

[File Package Command]

Parallel to INITRECORDS (page 17.38), INITRESOURCES writes expressions on a file to perform whatever initialization/allocation is necessary for the indicated resources, without writing the resource declaration itself.

# (COURIERPROGRAMS NAME 1 ... NAME N)

[File Package Command]

Each  $NAME_i$  is the name of a Courier program (see page 31.15). Writes expressions which will redeclare the Courier program when the file is loaded.

#### (TEMPLATES LITATOM<sub>1</sub> ... LITATOM<sub>N</sub>)

[File Package Command]

Each  $LITATOM_i$  is a litatom which has a Masterscope template (see page 19.21). Writes expressions which will restore the templates when the file is loaded.

#### (FILES FILE 1 ... FILE N)

[File Package Command]

Used to specify auxiliary files to be loaded in when the file is loaded. Dumps an expression calling FILESLOAD (page 17.9), with  $FILE_1 \dots FILE_N$  as the arguments. FILESLOAD interprets  $FILE_1 \dots FILE_N$  as files to load, possibly interspersed with lists used to specify certain loading options.

# (FILEPKGCOMS LITATOM<sub>1</sub> ... LITATOM<sub>N</sub>)

[File Package Command]

Each litatom  $LITATOM_i$  is either the name of a user-defined file package command or a user-defined file package type (or both). Writes expressions which will restore each command/type.

	If $LITATOM_i$ is not a file package command or type, a warning message "no FILE PACKAGE COMMAND for $LITATOM_i$ " is printed.				
(* . TEXT)	[File Package Command]				
	Used for inserting comments in a file. The file package command is simply written on the output file; it will be ignored when the file is loaded.				
•	If the first element of <i>TEXT</i> is another *, a form-feed is printed on the file before the comment.				
(P EXP <sub>1</sub> EXP <sub>N</sub> )	[File Package Command]				
	Writes each of the expressions <i>EXP</i> <sub>1</sub> <i>EXP</i> <sub>N</sub> on the output file, where they will be evaluated when the file is loaded.				
(E FORM <sub>1</sub> FORM <sub>N</sub> )	[File Package Command]				
	Each of the forms $FORM_1$ $FORM_N$ is evaluated at output time when MAKEFILE interpretes this file package command.				
(COMS $COM_1 COM_N$ )	[File Package Command]				
	Each of the commands $COM_1$ $COM_N$ is interpreted as a file package command.				
(ORIGINAL COM <sub>1</sub> COM <sub>N</sub>	(File Package Command)				
	Each of the commands $COM_i$ will be interpreted as a file package command without regard to any file package macros (as defined by the MACRO property of the FILEPKGCOM function, page 17.47). Useful for redefining a built-in file package command in terms of itself.				
	Note that some of the "built-in" file package commands are defined by file package macros, so interpreting them (or new user-defined file package commands) with ORIGINAL will fail. ORIGINAL was never intended to be used outside of a file package command macro.				

# 17.9.5 **DECLARE**:

# (DECLARE: . FILEPKGCOMS/FLAGS)

[File Package Command]

Normally expressions written onto a symbolic file are (1) evaluated when loaded; (2) copied to the compiled file when the symbolic file is compiled (see page 18.1); and (3) not evaluated at compile time. **DECLARE**: allows the user to override these defaults.

FILEPKGCOMS/FLAGS is a list of file package commands, possibly interspersed with "tags". The output of those file package commands within FILEPKGCOMS/FLAGS is embedded in a DECLARE: expression, along with any tags that are specified. For example, (DECLARE: EVAL@COMPILE DONTCOPY (FNS ...) (PROP ...)) would produce (DECLARE: EVAL@COMPILE DONTCOPY (DEFINEQ ...) (PUTPROPS ...)). DECLARE: is defined as an nlambda nospread function, which processes its arguments by evaluating or not evaluating each expression depending on the setting of internal state variables. The initial setting is to evaluate, but this can be overridden by specifying the DONTEVAL@LOAD tag.

**DECLARE:** expressions are specially processed by the compiler. For the purposes of compilation, **DECLARE:** has two principal applications: (1) to specify forms that are to be evaluated at compile time, presumably to affect the compilation, e.g., to set up macros; and/or (2) to indicate which expressions appearing in the symbolic file are *not* to be copied to the output file. (Normally, expressions are *not* evaluated and *are* copied.) Each expression in **CDR** of a **DECLARE:** form is either evaluated/not-evaluated and copied/not-copied depending on the settings of two internal state variables, initially set for copy and not-evaluate. These state variables can be reset for the remainder of the expressions in the **DECLARE:** by means of the tags **DONTCOPY, EVAL@COMPILE**, etc.

The tags are:

EVAL@LOAD
DOEVAL@LOAD

Evaluate the following forms when the file is loaded (unless overridden by DONTEVAL@LOAD).

DONTEVAL@LOAD

Do not evaluate the following forms when the file is loaded.

**EVAL@LOADWHEN** 

This tag can be used to provide conditional evaluation. The value of the expression immediately following the tag determines whether or not to evaluate subsequent expressions when loading. ... EVAL@LOADWHEN T ... is equivalent to ... EVAL@LOAD ...

COPY

DOCOPY

When compiling, copy the following forms into the compiled file

**DONTCOPY** 

When compiling, do not copy the following forms into the compiled file.

Note: If the file package commands following DONTCOPY include record declarations for datatypes, or records with initialization forms, it is necessary to include a INITRECORDS file package command (page 17.38) outside of the DONTCOPY form so that the initialization information is copied. For example, if FOO was defined as a datatype,

(DECLARE: DONTCOPY (RECORDS FOO))

(INITRECORDS FOO)

would copy the data type declaration for FOO, but would not

copy the whole record declaration.

When compiling, if the next form evaluates to non-NIL, copy the COPYWHEN

following forms into the compiled file.

**EVAL@COMPILE** DOEVAL@COMPILE

When compiling, evaluate the following forms.

DONTEVAL@COMPILE

When compiling, do not evaluate the following forms.

**EVAL@COMPILEWHEN** 

When compiling, if the next form evaluates to non-NIL, evaluate the following forms.

**FIRST** 

For expressions that are to be copied to the compiled file, the tag FIRST can be used to specify that the following expressions in the DECLARE: are to appear at the front of the compiled file, before anything else except the FILECREATED expressions (see page 17.51). For example, (DECLARE: COPY FIRST (P (PRINT MESS1 T)) NOTFIRST (P (PRINT MESS2 T))) will cause (PRINT MESS1 T) to appear first in the compiled file, followed by any functions, then

(PRINT MESS2 T).

**NOTFIRST** 

Reverses the effect of FIRST.

The value of DECLARETAGSLST is a list of all the tags used in **DECLARE:** expressions. If a tag not on this list appears in a DECLARE: file package command, spelling correction is performed using DECLARETAGSLST as a spelling list.

Note that the function LOADCOMP (page 17.8) provides a convenient way of obtaining information from the DECLARE: expressions in a file, without reading in the entire file. This information may be used for compiling other files.

(BLOCKS BLOCK 1 ... BLOCK N)

[File Package Command]

For each BLOCK, writes a DECLARE: expression which the block compile functions interpret as a block declaration. See page 18.17.

# 17.9.6 Exporting Definitions

When building a large system in Interlisp, it is often the case that there are record definitions, macros and the like that are needed by several different system files when running, analyzing and compiling the source code of the system, but which are not needed for running the compiled code. By using the DECLARE: file package command with tag DONTCOPY (page 17.40), these definitions can be kept out of the compiled files, and hence out of the system constructed by loading the compiled files files into

Interlisp. This saves loading time, space in the resulting system, and whatever other overhead might be incurred by keeping those definitions around, e.g., burden on the record package to consider more possibilities in translating record accesses, or conflicts between system record fields and user record fields.

However, if the implementor wants to debug or compile code in the resulting system, the definitions are needed. And even if the definitions had been copied to the compiled files, a similar problem arises if one wants to work on system code in a regular Interlisp environment where none of the system files had been loaded. One could mandate that any definition needed by more than one file in the system should reside on a distinguished file of definitions, to be loaded into any environment where the system files are worked on. Unfortunately, this would keep the definitions away from where they logically belong. The EXPORT mechanism is designed to solve this problem.

To use the mechanism, the implementor identifies any definitions needed by files other than the one in which the definitions reside, and wraps the corresponding file package commands in the EXPORT file package command. Thereafter, GATHEREXPORTS can be used to make a single file containing all the exports.

# (EXPORT $COM_1 ... COM_N$ )

[File Package Command]

This command is used for "exporting" definitions. Like COM, each of the commands  $COM_1$  ...  $COM_N$  is interpreted as a file package command. The commands are also flagged in the file as being "exported" commands, for use with GATHEREXPORTS (see page 17.43).

# (GATHEREXPORTS FROMFILES TOFILE FLG)

[Function]

FROMFILES is a list of files containing EXPORT commands. GATHEREXPORTS extracts all the exported commands from those files and produces a loadable file TOFILE containing them. If FLG = EVAL, the expressions are evaluated as they are gathered; i.e., the exports are effectively loaded into the current environment as well as being written to TOFILE.

#### (IMPORTFILE FILE RETURNFLG)

[Function]

If RETURNFLG is NIL, this loads any exported definitions from FILE into the current environment. If RETURNFLG is T, this returns a list of the exported definitions (evaluable expressions) without actually evaluating them.

#### (CHECKIMPORTS FILES NOASKFLG)

[Function]

Checks each of the files in FILES to see if any exists in a version newer than the one from which the exports in memory were

taken (GATHEREXPORTS and IMPORTFILE note the creation dates of the files involved), or if any file in the list has not had its exports loaded at all. If there are any such files, the user is asked for permission to IMPORTFILE each such file. If NOASKFLG is non-NIL, IMPORTFILE is performed without asking.

For example, suppose file FOO contains records R1, R2, and R3, macros BAR and BAZ, and constants CON1 and CON2. If the definitions of R1, R2, BAR, and BAZ are needed by files other than FOO, then the file commands for FOO might contain the command

(DECLARE: EVAL@COMPILE DONTCOPY

(EXPORT (RECORDS R1 R2)

(MACROS BAR BAZ))

(RECORDS R3)

(CONSTANTS BAZ))

None of the commands inside this DECLARE: would appear on FOO's compiled file, but (GATHEREXPORTS '(FOO) 'MYEXPORTS) would copy the record definitions for R1 and R2 and the macro definitions for BAR and BAZ to the file MYEXPORTS

#### 17.9.7 FileVars

In each of the file package commands described above, if the litatom \* follows the command type, the form following the \*, i.e., CADDR of the command, is evaluated and its value used in executing the command, e.g., (FNS \* (APPEND FNS1 FNS2)). When this form is a litatom, e.g. (FNS \* FOOFNS), we say that the variable is a "filevar". Note that (COMS \* FORM) provides a way of computing what should be done by MAKEFILE.

#### Example:

(RPAQQ FOOFNS (FOO1 FOO3 FOO3))

(DEFINEQ "definitions of FOO1, FOO2, and FOO3")
(RPAQQ FIE "value of FIE")
(PUTPROPS FOO1 MACRO PROPVALUE)
(PUTPROPS FOO2 MACRO PROPVALUE)
(MOVD (QUOTE FOO1) (QUOTE FIE1))
STOP

Note: For the PROP and IFPROP commands (page 17.37), the \* follows the property name instead of the command, e.g., (PROP MACRO \* FOOMACROS). Also, in the form (\* \* comment ...), the word comment is not treated as a filevar.

# 17.9.8 Defining New File Package Commands

A file package command is defined by specifying the values of certain properties. The user can specify the various attributes of a file package command for a new command, or respecify them for an existing command. The following properties are used:

#### **MACRO**

#### [File Package Command Property]

Defines how to dump the file package command. Used by MAKEFILE. Value is a pair (ARGS. COMS). The "arguments" to the file package command are substituted for ARGS throughout COMS, and the result treated as a list of file package commands. For example, following (FILEPKGCOM 'FOO 'MACRO '((X Y). COMS)), the file package command (FOO A B) will cause A to be substituted for X and B for Y throughout COMS, and then COMS treated as a list of commands.

The substitution is carried out by SUBPAIR (page 3.14), so that the "argument list" for the macro can also be atomic. For example, if (X . COMS) was used instead of ((X Y) . COMS), then the command (FOO A B) would cause (A B) to be substituted for X throughout COMS.

Note: Filevars are evaluated *before* substitution. For example, if the litatom \* follows *NAME* in the command, **CADDR** of the command is evaluated substituting in *COMS*.

#### **ADD**

#### [File Package Command Property]

Specifies how (if possible) to add an instance of an object of a particular type to a given file package command. Used by ADDTOFILE. Value is FN, a function of three arguments, COM, a file package command CAR of which is EQ to COMMANDNAME, NAME, a typed object, and TYPE, its type. FN should return T if it (undoably) adds NAME to COM, NIL if not. If no ADD property is specified, then the default is (1) if (CAR COM) = TYPE and (CADR COM) = \*, and (CADDR COM) is a filevar (i.e. a literal atom), add

NAME to the value of the filevar, or (2) if (CAR COM) = TYPE and (CADR COM) is not \*, add NAME to (CDR COM).

Actually, the function is given a fourth argument, *NEAR*, which if non-NIL, means the function should try to add the item after *NEAR*. See discussion of ADDTOFILES?, page 17.13.

#### DELETE

[File Package Command Property]

Specifies how (if possible) to delete an instance of an object of a particular type from a given file package command. Used by DELFROMFILES. Value is FN, a function of three arguments, COM, NAME, and TYPE, same as for ADD. FN should return T if it (undoably) deletes NAME from COM, NIL if not. If no DELETE property is specified, then the default is (1) (CAR COM) = TYPE and (CADR COM) = \*, and (CADDR COM) is a filevar (i.e. a literal atom), and NAME is contained in the value of the filevar, then remove NAME from the filevar, or (2) if (CAR COM) = TYPE and (CADR COM) is not \*, and NAME is contained in (CDR COM), then remove NAME from (CDR COM).

If FN returns the value of ALL, it means that the command is now "empty", and can be deleted entirely from the command list.

#### **CONTENTS**

[File Package Command Property]

#### CONTAIN

[File Package Command Property]

Determines whether an instance of an object of a given type is contained in a given file package command. Used by WHEREIS and INFILECOMS?. Value is FN, a function of three arguments, COM, a file package command CAR of which is EQ to COMMANDNAME, NAME, and TYPE. The interpretation of NAME is as follows: if NAME is NIL, FN should return a list of elements of type TYPE contained in COM. If NAME is T, FN should return T if there are any elements of type TYPE in COM. If NAME is an atom other than T or NIL, return T if NAME of type TYPE is contained in COM. Finally, if NAME is a list, return a list of those elements of type TYPE contained in COM that are also contained in NAME.

Note that it is sufficient for the **CONTENTS** function to simply return the list of items of type *TYPE* in command *COM*, i.e. it can in fact ignore the *NAME* argument. The *NAME* argument is supplied mainly for those situations where producing the entire list of items involves significantly more computation or creates more storage than simply determining whether a particular item (or any item) of type *TYPE* is contained in the command.

If a **CONTENTS** property is specified and the corresponding function application returns **NIL** and **(CAR** COM) = TYPE, then the operation indicated by NAME is performed (1) on the value

of (CADDR COM), if (CADR COM) = \*, otherwise (2) on (CDR COM). In other words, by specifying a CONTENTS property that returns NIL, e.g. the function NILL, the user specifies that a file package command of name FOO produces objects of file package type FOO and only objects of type FOO.

If the **CONTENTS** property is not provided, the command is simply expanded according to its **MACRO** definition, and each command on the resulting command list is then interrogated.

Note that if *COMMANDNAME* is a file package command that is used frequently, its expansion by the various parts of the system that need to interrogate files can result in a large number of **CONS**es and garbage collections. By informing the file package as to what this command actually does and does not produce via the **CONTENTS** property, this expansion is avoided. For example, suppose the user has a file package command called **GRAMMARS** which dumps various property lists but no functions. The file package could ignore this command when seeking information about **FNS**.

The function **FILEPKGCOM** is used to define new file package commands, or to change the properties of existing commands. Note that it is possible to redefine the attributes of system file package commands, such as **FNS** or **PROPS**, and to cause unpredictable results.

#### (FILEPKGCOM COMMANDNAME PROP 1 VAL 1 ... PROP N VAL N)

[NoSpread Function]

Nospread function for defining new file package commands, or changing properties of existing file package commands.  $PROP_i$  is one of of the property names described above;  $VAL_i$  is the value to be given that property of the file package command COMMANDNAME. Returns COMMANDNAME.

**(FILEPKGCOM COMMANDNAME PROP)** returns the value of the property *PROP*, without changing it.

**(FILEPKGCOM** *COMMANDNAME*) returns an alist of all of the defined properties of *COMMANDNAME*, using the property names as keys.

Note: Specifying TYPE as the litatom COM can be used to define one file package command as a synonym of another. For example, (FILEPKGCOM 'INITVARIABLES 'COM 'INITVARS) defines INITVARIABLES as a synonym for the file package command INITVARS.

# 17.10 Functions for Manipulating File Command Lists

The following functions may be used to manipulate filecoms. The argument *COMS* does *not* have to correspond to the filecoms for some file. For example, *COMS* can be the list of commands generated as a result of expanding a user defined file package command.

Note: The following functions will accept a file package command as a valid value for their *TYPE* argument, even if it does not have a corresponding file package type. User-defined file package commands are expanded as necessary.

#### (INFILECOMS? NAME TYPE COMS —)

[Function]

COMS is a list of file package commands, or a variable whose value is a list of file package commands. TYPE is a file package type. INFILECOMS? returns T if NAME of type TYPE is "contained" in COMS.

If NAME = NIL, INFILECOMS? returns a list of all elements of type TYPE.

If NAME = T, INFILECOMS? returns T if there are any elements of type TYPE in COMS.

#### (ADDTOFILE NAME TYPE FILE NEAR LISTNAME)

[Function]

Adds NAME of type TYPE to the file package commands for FILE. If NEAR is given and it is the name of an item of type TYPE already on FILE, then NAME is added to the command that dumps NEAR. If LISTNAME is given and is the name of a list of items of TYPE items on FILE, then NAME is added to that list. Uses ADDTOCOMS and MAKENEWCOM. Returns FILE. ADDTOFILE is undoable.

#### (DELFROMFILES NAME TYPE FILES)

[Function]

Deletes all instances of NAME of type TYPE from the filecoms for each of the files on FILES. If FILES is a non-NIL litatom, (LIST FILES) is used. FILES = NIL defaults to FILELST. Returns a list of files from which NAME was actually removed. Uses DELFROMCOMS. DELFROMFILES is undoable.

Note: Deleting a function will also remove the function from any **BLOCKS** declarations in the filecoms.

#### (ADDTOCOMS COMS NAME TYPE NEAR LISTNAME)

[Function]

Adds NAME as a TYPE to COMS, a list of file package commands or a variable whose value is a list of file package commands. Returns NIL if ADDTOCOMS was unable to find a command appropriate for adding NAME to COMS. NEAR and LISTNAME

are described in the discussion of ADDTOFILE. ADDTOCOMS is undoable.

Note that the exact algorithm for adding commands depends the particular command itself. See discussion of the ADD property, in the description of FILEPKGCOM, page 17.47.

Note: ADDTOCOMS will not attempt to add an item to any command which is inside of a DECLARE: unless the user specified a specific name via the LISTNAME or NEAR option of ADDTOFILES?.

#### (DELFROMCOMS COMS NAME TYPE)

[Function]

Deletes *NAME* as a *TYPE* from *COMS*. Returns **NIL** if **DELFROMCOMS** was unable to modify *COMS* to delete *NAME*. **DELFROMCOMS** is undoable.

#### (MAKENEWCOM NAME TYPE — —)

[Function]

Returns a file package command for dumping *NAME* of type *TYPE*. Uses the procedure described in the discussion of **NEWCOM**, page 17.32.

#### (MOVETOFILE TOFILE NAME TYPE FROMFILE)

[Function]

Moves the definition of *NAME* as a *TYPE* from *FROMFILE* to *TOFILE* by modifying the file commands in the appropriate way (with **DELFROMFILES** and **ADDTOFILE**).

Note that if *FROMFILE* is specified, the definition will be retrieved from that file, even if there is another definition currently in the user's environment.

#### (FILECOMSLST FILE TYPE —)

[Function]

Returns a list of all objects of type TYPE in FILE.

#### (FILEFNSLST FILE)

[Function]

Same as (FILECOMSLST FILE 'FNS).

#### (FILECOMS FILE TYPE)

[Function]

Returns (PACK\* FILE (OR TYPE 'COMS)). Note that (FILECOMS 'FOO) returns the litatom FOOCOMS, not the value of FOOCOMS.

#### (SMASHFILECOMS FILE)

[Function]

Maps down (FILECOMSLST FILE 'FILEVARS) and sets to NOBIND all filevars (see page 17.44), i.e. any variable used in a command of the form (COMMAND \* VARIABLE). Also sets (FILECOMS FILE) to NOBIND. Returns FILE.

# 17.11 Symbolic File Format

The file package manipulates symbolic files in a particular format. This format is defined so that the information in the file is easily readable when the file is listed, as well as being easily manipulated by the file package functions. In general, there is no reason for the user to manually change the contents of a symbolic file. However, in order to allow users to extend the file package, this section describes some of the functions used to write symbolic files, and other matters related to their format.

# (PRETTYDEF PRITYFNS PRITYFILE PRITYCOMS REPRINTFNS SOURCEFILE CHANGES) [Function]

Writes a symbolic file in **PRETTYPRINT** format for loading, using **FILERDTBL** as its read table. **PRETTYDEF** returns the name of the symbolic file that was created.

PRETTYDEF operates under a RESETLST (see page 14.24), so if an error occurs, or a control-D is typed, all files that PRETTYDEF has opened will be closed, the (partially complete) file being written will be deleted, and any undoable operations executed will be undone. The RESETLST also means that any RESETSAVEs executed in the file package commands will also be protected.

PRTTYFNS is an optional list of function names. It is equivalent to including (FNS \* PRTTYFNS) in the file package commands in PRTTYCOMS. PRTTYFNS is an anachronism from when PRETTYDEF did not use a list of file package commands, and should be specified as NIL.

PRTTYFILE is the name of the file on which the output is to be written. If PRTTYFILE = NIL, the primary output file is used. If PRTTYFILE is atomic the file is opened if not already open, and it becomes the primary output file. PRTTYFILE is closed at end of PRETTYDEF, and the primary output file is restored. Finally, if PRTTYFILE is a list, CAR of PRTTYFILE is assumed to be the file name, and is opened if not already open. In this case, the file is left open at end of PRETTYDEF.

PRTTYCOMS is a list of file package commands interpreted as described on page 17.32. If PRTTYCOMS is atomic, its top level value is used and an RPAQQ is written which will set that atom to the list of commands when the file is subsequently loaded. A PRETTYCOMPRINT expression (see below) will also be written which informs the user of the named atom or list of commands when the file is subsequently loaded. In addition, if any of the functions in the file are nlambda functions, PRETTYDEF will automatically print a DECLARE: expression suitable for informing the compiler about these functions, in case the user recompiles the file without having first loaded the nlambda functions (see page 18.8).

REPRINTENS and SOURCEFILE are for use in conjunction with remaking a file (see page 17.15). REPRINTENS can be a list of functions to be prettyprinted, or EXPRS, meaning prettyprint all functions with EXPR definitions, or ALL meaning prettyprint all functions either defined as EXPRs, or with EXPR properties. Note that doing a remake with REPRINTFNS = NIL makes sense if there have been changes in the file, but not to any of the functions, e.g., changes to variables or property lists. SOURCEFILE is the name of the file from which to copy the definitions for those functions that are not going to be prettyprinted, i.e., those not specified by REPRINTENS. SOURCEFILE = T means to use most recent version (i.e., highest number) of PRTTYFILE, the second argument to PRETTYDEF. If SOURCEFILE cannot be found, PRETTYDEF prints the message "FILE NOT FOUND, SO IT WILL BE WRITTEN ANEW", and proceeds as it does when REPRINTENS and SOURCEFILE are both NIL.

**PRETTYDEF** calls **PRETTYPRINT** with its second argument **PRETTYDEFLG** = **T**, so whenever **PRETTYPRINT** starts a new function, it prints (on the terminal) the name of that function if more than 30 seconds (real time) have elapsed since the last time it printed the name of a function.

Note that normally if **PRETTYPRINT** is given a litatom which is not defined as a function but is known to be on one of the files noticed by the file package, **PRETTYPRINT** will load in the definition (using **LOADFNS**) and print it. This is not done when **PRETTYPRINT** is called from **PRETTYDEF**.

#### (PRINTFNS X ---)

[Function]

X is a list of functions. **PRINTFNS** prettyprints a **DEFINEQ** epression that defines the functions to the primary output stream using the primary read table. Used by **PRETTYDEF** to implement the **FNS** file package command.

# (PRINTDATE FILE CHANGES)

[Function]

Prints the **FILECREATED** expression at beginning of **PRETTYDEF** files. **CHANGES** used by the file package.

#### (FILECREATED X)

[NLambda NoSpread Function]

Prints a message (using LISPXPRINT) followed by the time and date the file was made, which is (CAR X). The message is the value of PRETTYHEADER, initially "FILE CREATED". If PRETTYHEADER = NIL, nothing is printed. (CDR X) contains information about the file, e.g., full name, address of file map, list of changed items, etc. FILECREATED also stores the time and date the file was made on the property list of the file under the property FILEDATES and performs other initialization for the file package.

(PRETTYCOMPRINT X)					[NLambda F	unction]
	Prints PRETTY	X HEAD	(unevaluated) DER = NIL.	using	LISPXPRINT,	unless
PRETTYHEADER					[\	/ariable]
	Value is the message printed by FILECREATED. PRETTYHEADER is					
	initially "FILE CREATED". If PRETTYHEADER = NIL, neither					
	FILECREATED nor PRETTYCOMPRINT will print anything. Thus,					
•	setting PRETTYHEADER to NIL will result in "silent loads".					
	PRETTYHEADER is reset to NIL during greeting (page 12.1).					
/FU FOUANCES SU S TYPE					ſe	
(FILECHANGES FILE TYPE)				1.1		unction]
	Returns a list of the changed objects of file package type TYPE					
	from the FILECREATED expression of FILE. If TYPE = NIL, returns					
	an alist of all of the changes, with the file package types as the CARs of the elements					es as the
(FILEDATE FILE —)					ſF	unction]
(TEEDATE TIEL)	Returns the file date contained in the FILECREATED expression of					
	FILE.				- CAPITO CAPIT	
(LISPSOURCEFILEP FILE)					(F	unction]
	Returns a non-NIL value if FILE is an Interlisp source file, NIL otherwise.					

# 17.11.1 Copyright Notices

The system has a facility for automatically printing a copyright notice near the front of files, right after the FILECREATED expression, specifying the years it was edited and the copyright owner. The format of the copyright notice is:

# (\* Copyright (c) 1981 by Foo Bars Corporation)

Once a file has a copyright notice then every version will have a new copyright notice inserted into the file without user intervention. (The copyright information necessary to keep the copyright up to date is stored at the end of the file.).

Any year the file has been edited is considered a "copyright year" and therefore kept with the copyright information. For example, if a file has been edited in 1981, 1982, and 1984, then the copyright notice would look like:

#### (\* Copyright (c) 1981,1982,1984 by Foo Bars Corporation)

When a file is made, if it has no copyright information, the system will ask the user to specify the copyright owner (if COPYRIGHTFLG = T). The user may specify one of the names

17 52

from **COPYRIGHTOWNERS**, or give one of the following responses:

- (1) Type a left-square-bracket. The system will then prompt for an arbitrary string which will be used as the owner-string
- (2) Type a right-square-bracket, which specifies that the user really does not want a copyright notice.
- (3) Type "NONE" which specifies that this file should never have a copyright notice.

For example, if COPYRIGHTOWNERS has the value

((BBN "Bolt Beranek and Newman Inc.")
(XEROX "Xerox Corporation"))

then for a new file FOO the following interaction will take place:

Do you want to Copyright FOO? Yes Copyright owner: (user typed ?)

one of:

BBN - Bolt Beranek and Newman Inc.

**XEROX - Xerox Corporation** 

NONE - no copyright ever for this file

[ - new copyright owner -- type one line of text

] - no copyright notice for this file now

#### Copyright owner: BBN

Then "Foo Bars Corporation" in the above copyright notice example would have been "Bolt Beranek and Newman Inc."

The following variables control the operation of the copyright facility:

#### COPYRIGHTFLG

[Variable]

The value of **COPYRIGHTFLG** determines whether copyright information is maintained in files. Its value is interpreted as follows:

- NIL The system will preserve old copyright information, but will not ask the user about copyrighting new files. This is the default value of COPYRIGHTFLG.
  - T When a file is made, if it has no copyright information, the system will ask the user to specify the copyright owner.

**NEVER** The system will neither prompt for new copyright information nor preserve old copyright information.

#### **DEFAULT**

The value of **DEFAULTCOPYRIGHTOWNER** (below) is used for putting copyright information in files that don't have any other copyright. The prompt "Copyright owner for file xx:" will still be printed, but the default will be filled in immediately.

#### **COPYRIGHTOWNERS**

[Variable]

**COPYRIGHTOWNERS** is a list of entries of the form (KEY OWNERSTRING), where KEY is used as a response to ASKUSER and OWNERSTRING is a string which is the full identification of the owner.

#### **DEFAULTCOPYRIGHTOWNER**

[Variable]

If the user does not respond in **DWIMWAIT** seconds to the copyright query, the value of **DEFAULTCOPYRIGHTOWNER** is used.

### 17.11.2 Functions Used Within Source Files

The following functions are normally only used within symbolic files, to set variable values, property values, etc. Most of these have special behavior depending on file package variables.

#### (RPAQ VAR VALUE)

[NLambda Function]

An nlambda function like **SETQ** that sets the top level binding of *VAR* (unevaluated) to *VALUE*.

#### (RPAQQ VAR VALUE)

[NLambda Function]

An nlambda function like **SETQQ** that sets the top level binding of *VAR* (unevaluated) to *VALUE* (unevaluated).

### (RPAQ? VAR VALUE)

[NLambda Function]

Similar to RPAQ, except that it does nothing if VAR already has a top level value other than NOBIND. Returns VALUE if VAR is reset, otherwise NIL.

**RPAQ**, **RPAQQ**, and **RPAQ?** generate errors if X is not a litatom. All are affected by the value of **DFNFLG** (page 10.10). If **DFNFLG = ALLPROP** (and the value of *VAR* is other than **NOBIND**), instead of setting X, the corresponding value is stored on the property list of *VAR* under the property **VALUE**. All are undoable.

#### (ADDTOVAR $VAR X_1 X_2 ... X_N$ )

[NLambda NoSpread Function]

Each  $X_i$  that is not a member of the value of VAR is added to it, i.e. after ADDTOVAR completes, the value of VAR will be (UNION (LIST  $X_1 X_2 ... X_N$ ) VAR). ADDTOVAR is used by PRETTYDEF for implementing the ADDVARS command. It performs some file package related operations, i.e. "notices" that VAR has been changed. Returns the atom VAR (not the value of VAR).

# (APPENDTOVAR VAR X<sub>1</sub> X<sub>2</sub> ... X<sub>N</sub>)

[NLambda NoSpread Function]

Similar to ADDTOVAR, except that the values are added to the end tof the list, rather than at the beginning.

# (PUTPROPS ATM PROP<sub>1</sub> VAL<sub>1</sub> ... PROP<sub>N</sub> VAL<sub>N</sub>)

[NLambda NoSpread Function]

Nlambda nospread version of **PUTPROP** (none of the arguments are evaluated). For i=1...N, puts property  $PROP_i$ , value  $VAL_i$ , on the property list of ATM. Performs some file package related operations, i.e., "notices" that the corresponding properties have been changed.

# (SAVEPUT ATM PROP VAL)

[Function]

Same as PUTPROP, but marks the corresponding property value as having been changed (used by the file package).

# 17.11.3 File Maps

A file map is a data structure which contains a symbolic 'map' of the contents of a file. Currently, this consists of the begin and end byte address (see GETFILEPTR, page 25.19) for each DEFINEQ expression in the file, the begin and end address for each function definition within the DEFINEQ, and the begin and end address for each compiled function.

MAKEFILE, PRETTYDEF, LOADFNS, RECOMPILE, and numerous other system functions depend heavily on the file map for efficient operation. For example, the file map enables LOADFNS to load selected function definitions simply by setting the file pointer to the corresponding address using SETFILEPTR, and then performing a single READ. Similarly, the file map is heavily used by the "remake" option of MAKEFILE (page 17.15): those function definitions that have been changed since the previous version are prettyprinted; the rest are simply copied from the old file to the new one, resulting in a considerable speedup.

Whenever a file is written by MAKEFILE, a file map for the new file is built. Building the map in this case essentially comes for free, since it requires only reading the current file pointer before and after each definition is written or copied. However, building the map does require that PRETTYPRINT know that it is printing a DEFINEQ expression. For this reason, the user should never print a DEFINEQ expression onto a file himself, but should instead always use the FNS file package command (page 17.34).

The file map is stored on the property list of the root name of the file, under the property FILEMAP. In addition, MAKEFILE writes the file map on the file itself. For cosmetic reasons, the file map is written as the last expression in the file. However, the address of the file map in the file is (over)written into the FILECREATED

expression that appears at the beginning of the file so that the file map can be rapidly accessed without having to scan the entire file. In most cases, LOAD and LOADFNS do not have to build the file map at all, since a file map will usually appear in the corresponding file, unless the file was written with BUILDMAPFLG = NIL, or was written outside of Interlisp.

Currently, file maps for *compiled* files are not written onto the files themselves. However, LOAD and LOADFNS will build maps for a compiled file when it is loaded, and store it on the property FILEMAP. Similary, LOADFNS will obtain and use the file map for a compiled file, when available.

The use and creation of file maps is controlled by the following variables:

#### BUILDMAPFLG

[Variable]

Whenever a file is read by LOAD or LOADFNS, or written by MAKEFILE, a file map is automatically built unless BUILDMAPFLG = NIL. (BUILDMAPFLG is initially T.)

While building the map will not help the first reference to a file, it will help in future references. For example, if the user performs (LOADFROM 'FOO) where FOO does not contain a file map, the LOADFROM will be (slightly) slower than if FOO did contain a file map, but subsequent calls to LOADFNS for this version of FOO will be able to use the map that was built as the result of the LOADFROM, since it will be stored on FOO's FILEMAP property.

#### **USEMAPFLG**

[Variable]

If USEMAPFLG = T (the initial setting), the functions that use file maps will first check the FILEMAP property to see if a file map for this file was previously obtained or built. If not, the first expression on the file is checked to see if it is a FILECREATED expression that also contains the address of a file map. If the file map is not on the FILEMAP property or in the file, a file map will be built (unless BUILDMAPFLG = NIL).

If **USEMAPFLG = NIL**, the **FILEMAP** property and the file will not be checked for the file map. This allows the user to recover in those cases where the file and its map for some reason do not agree. For example, if the user uses a text editor to change a symbolic file that contains a map (not recommended), inserting or deleting just one character will throw that map off. The functions which use file maps contain various integrity checks to enable them to detect that something is wrong, and to generate the error **FILEMAP DOES NOT AGREE WITH CONTENTS OF FILE**. In such cases, the user can set **USEMAPFLG** to **NIL**, causing the map contained in the file to be ignored, and then reexecute the operation.

TABLE OF CONTENTS TOC.1

[This page intentionally left blank]

TOC.2 TABLE OF CONTENTS

The compiler is contained in the standard Interlisp system. It may be used to compile functions defined in the user's Interlisp system, or to compile definitions stored in a file. The resulting compiled code may be stored as it is compiled, so as to be available for immediate use, or it may be written onto a file for subsequent loading.

The most common way to use the compiler is to use one of the file package functions, such as MAKEFILE (page 17.10), which automatically updates source files, and produces compiled versions. However, it is also possible to compile individual functions defined in the user's Interlisp system, by directly calling the compiler using functions such as COMPILE (page 18.14). No matter how the compiler is called, the function COMPSET is called which asks the user certain questions concerning the compilation. (COMPSET sets the free variables LAPFLG, STRF, SVFLG, LCFIL and LSTFIL which determine various modes of operation.) Those that can be answered "yes" or "no" can be answered with YES, Y, or T for "yes"; and NO, N, or NIL for "no". The questions are:

- LISTING? This asks whether to generate a listing of the compiled code.

  The LAP and machine code are usually not of interest but can be helpful in debugging macros. Possible answers are:
  - 1 Prints output of pass 1, the LAP macro code.
  - 2 Prints output of pass 2, the machine code.
  - YES Prints output of both passes.
  - NO Prints no listings.

The variable LAPFLG is set to the answer.

FILE: This question (which only appears if the answer to LISTING? is affirmative) ask where the compiled code listing(s) should be written. Answering T will print the listings at the terminal. The variable LSTFIL is set to the answer.

REDEFINE?

This question asks whether the functions compiled should be redefined to their compiled definitions. If this is answered YES, the compiled code is stored and the function definition changed, otherwise the function definition remains unchanged.

Note: The compiler does NOT respect the value of **DFNFLG** (page 10.10) when it redefines functions to their compiled definitions. Therefore, if you set **DFNFLG** to **PROP** to completely avoid

inadvertantly redefining something in your running system, you MUST not answer YES to this question.

The variable STRF is set to T (if this is answered YES) or NIL.

#### **SAVE EXPRS?**

This question asks whether the original defining EXPRs of functions should be saved. If answered YES, then before redefining a function to its compiled definition, the EXPR definition is saved on the property list of the function name. Otherwise they are discarded.

It is very useful to save the EXPR definitions, just in case the compiled function needs to be changed. The editing functions will retrieve this saved definition if it exists, rather than reading from a source file.

The variable SVFLG is set to T (if this is answered YES) or NIL.

#### **OUTPUT FILE?**

This question asks whether (and where) the compiled definitions should be written into a file for later loading. If you answer with the name of a file, that file will be used. If you answer Y or YES, you will be asked the name of the file. If the file named is already open, it will continue to be used. If you answer T or TTY:, the output will be typed on the teletype (not particularly useful). If you answer N, NO, or NIL, output will not be done.

The variable LCFIL is set to the name of the file.

In order to make answering these questions easier, there are four other possible answers to the LISTING? question, which specify common compiling modes:

- **S** Same as last setting. Uses the same answers to compiler questions as given for the last compilation.
- F Compile to File, without redefining functions.
- ST STore new definitions, saving EXPR definitions.
- STF STore new definitions; Forget EXPR definitions.

Implicit in these answers are the answers to the questions on disposition of compiled code and EXPR definitions, so the questions REDEFINE? and SAVE EXPRS? would not be asked if these answers were given. OUTPUT FILE? would still be asked, however. For example:

←COMPILE((FACT FACT1 FACT2))
LISTING? ST
OUTPUT FILE? FACT.DCOM
(FACT COMPILING)

(FACT REDEFINED)

(FACT2 REDEFINED)

#### (FACT FACT1 FACT2)

**←** 

This process caused the functions FACT, FACT1, and FACT2 to be compiled, redefined, and the compiled definitions also written on the file FACT.DCOM for subsequent loading.

# **18.1 Compiler Printout**

In Interlisp-D, for each function *FN* compiled, whether by **TCOMPL**, **RECOMPILE**, or **COMPILE**, the compiler prints:

 $(FN(ARG_1 ... ARG_N) (uses: VAR_1 ... VAR_N) (calls: FN_1 ... FN_N))$ 

The message is printed at the beginning of the second pass of the compilation of FN.  $(ARG_1 ... ARG_N)$  is the list of arguments to FN; following "uses:" are the free variables referenced or set in FN (not including global variables); following "calls:" are the undefined functions called within FN.

If the compilation of FN causes the generation of one or more auxiliary functions (see page 18.10), a compiler message will be printed for these functions before the message for FN, e.g.,

(FOOA0027 (X) (uses: XX)) (FOO (A B))

When compiling a block, the compiler first prints (BLKNAME BLKFN<sub>1</sub> BLKFN<sub>2</sub> ...). Then the normal message is printed for the entire block. The names of the arguments to the block are generated by suffixing "#" and a number to the block name, e.g., (FOOBLOCK (FOOBLOCK#0 FOOBLOCK#1) FREE-VARIABLES). Then a message is printed for each entry to the block.

In addition to the above output, both RECOMPILE and BRECOMPILE print the name of each function that is being copied from the old compiled file to the new compiled file. The normal compiler message is printed for each function that is actually compiled.

The compiler prints out error messages when it encounters problems compiling a function. For example:

----- In BAZ: \*\*\*\*\* (BAZ - illegal RETURN)

The above error message indicates that an "illegal RETURN" compiler error occurred while trying to compile the function BAZ. Some compiler errors cause the compilation to terminate, producing nothing; however, there are other compiler errors

which do not stop compilation. The compiler error messages are described on page 18.22.

Compiler printout and error messages go to the file COUTFILE, initially T. COUTFILE can also be set to the name of a file opened for output, in which case all compiler printout will go to COUTFILE, i.e. the compiler will compile "silently." However, any error messages will be printed to both COUTFILE as well as T.

# 18.2 Global Variables

Variables that appear on the list GLOBALVARS, or have the property GLOBALVAR with value T, or are declared with the GLOBALVARS file package command (page 17.37), are called global variables. Such variables are always accessed through their top level value when they are used freely in a compiled function. In other words, a reference to the value of a global variable is equivalent to calling GETTOPVAL (page 2.4) on the variable, regardless of whether or not it is bound in the current access chain. Similarly, (SETQ VARIABLE VALUE) will compile as (SETTOPVAL (QUOTE VARIABLE) VALUE).

All system parameters, unless otherwise specified, are declared as global variables. Thus, *rebinding* these variables in a deep bound system (like Interlisp-D) will not affect the behavior of the system: instead, the variables must be *reset* to their new values, and if they are to be restored to their original values, reset again. For example, the user might write

(SETQ GLOBALVARIABLE NEWVALUE) FORM (SETQ GLOBALVARIABLE OLDVALUE)

Note that in this case, if an error occurred during the evaluation of *FORM*, or a control-D was typed, the global variable would not be restored to its original value. The function **RESETVAR** (page 14.25) provides a convenient way of resetting global variables in such a way that their values are restored even if an error occurred or control-D is typed.

Note: The variables that a given function accesses as global variables can be determined by using the function CALLS (page 19.22).

# 18.3 Local Variables and Special Variables

In normal compiled and interpreted code, all variable bindings are accessible by lower level functions because the variable's name is associated with its value. We call such variables special variables, or specvars. As mentioned earlier, the block compiler normally does not associate names with variable values. Such unnamed variables are not accessible from outside the function which binds them and are therefore local to that function. We call such unnamed variables local variables, or localvars.

The time economies of local variables can be achieved without block compiling by use of declarations. Using local variables will increase the speed of compiled code; the price is the work of writing the necessary specvar declarations for those variables which need to be accessed from outside the block.

LOCALVARS and SPECVARS are variables that affect compilation. During regular compilation, SPECVARS is normally T, and LOCALVARS is NIL or a list. This configuration causes all variables bound in the functions being compiled to be treated as special except those that appear on LOCALVARS. During block compilation, LOCALVARS is normally T and SPECVARS is NIL or a list. All variables are then treated as local except those that appear on SPECVARS.

Declarations to set LOCALVARS and SPECVARS to other values, and therefore affect how variables are treated, may be used at several levels in the compilation process with varying scope.

- (1) The declarations may be included in the filecoms of a file, by using the LOCALVARS and SPECVARS file package commands (page 17.37). The scope of the declaration is then the entire file:
- ... (LOCALVARS . T) (SPECVARS X Y) ...
- (2) The declarations may be included in block declarations; the scope is then the block, e.g.,

#### (BLOCKS ((FOOBLOCK FOO FIE (SPECVARS . T) (LOCALVARS X)))

(3) The declarations may also appear in individual functions, or in PROG's or LAMBDA's within a function, using the DECLARE function. In this case, the scope of the declaration is the function or the PROG or LAMBDA in which it appears. LOCALVARS and SPECVARS declarations must appear immediately after the variable list in the function, PROG, or LAMBDA, but intervening comments are permitted. For example:

```
(DEFINEQ ((FOO
(LAMBDA (X Y)
(DECLARE (LOCALVARS Y))
(PROG (X Y Z)
(DECLARE (LOCALVARS X))
...]
```

If the above function is compiled (non-block), the outer X will be special, the X bound in the PROG will be local, and both bindings of Y will be local.

Declarations for LOCALVARS and SPECVARS can be used in two ways: either to cause variables to be treated the same whether the function(s) are block compiled or compiled normally, or to affect one compilation mode while not affecting the default in the other mode. For example:

```
(LAMBDA (X Y)
(DECLARE (SPECVARS . T))
(PROG (Z) ... ]
```

will cause X, Y, and Z to be specvars for both block and normal compilation while

```
(LAMBDA (X Y)
(DECLARE (SPECVARS X))
... 1
```

will make X a specvar when block compiling, but when regular compiling the declaration will have no effect, because the default value of specvars would be T, and therefore both X and Y will be specvars by default.

Although LOCALVARS and SPECVARS declarations have the same form as other components of block declarations such as (LINKFNS.T), their operation is somewhat different because the two variables are not independent. (SPECVARS.T) will cause SPECVARS to be set to T, and LOCALVARS to be set to NIL. (SPECVARS V1 V2 ...) will have no effect if the value of SPECVARS is T, but if it is a list (or NIL), SPECVARS will be set to the union of its prior value and (V1 V2 ...). The operation of LOCALVARS is analogous. Thus, to affect both modes of compilation one of the two (LOCALVARS or SPECVARS) must be declared T before specifying a list for the other.

Note: The variables that a given function binds as local variables or accesses as special variables can be determined by using the function CALLS (page 19.22).

Note: LOCALVARS and SPECVARS declarations affect the compilation of local variables within a function, but the arguments to functions are always accessable as specvars. This can be changed by re-defining the following function:

#### (DASSEM.SAVELOCALVARS FN)

[Function]

This function is called by the compiler to determine whether argument information for FN should be written on the compiled file for FN. If it returns NIL, the argument information is not saved, and the function is stored with arguments U, V, W, etc instead of the originals.

Initially, DASSEM.SAVELOCALVARS is defined to return T. (MOVD 'NILL 'DASSEM.SAVELOCALVARS) causes the compiler to retain no local variable or argument names. Alternatively, DASSEM.SAVELOCALVARS could be redefined as a more complex predicate, to allow finer discrimination.

# 18.4 Constants

Interlisp allows the expression of constructions which are intended to be description of their constant values. The following functions are used to define constant values. The function **SELECTC** (page 9.7) provides a mechanism for comparing a value to a number of constants.

#### (CONSTANT X)

[Function]

This function enables the user to define that the expression X should be treated as a "constant" value. When CONSTANT is interpreted, X is evaluted each time it is encountered. If the CONSTANT form is compiled, however, the expression will be evaluated only once.

If the value of X has a readable print name, then it will be evaluated at compile-time, and the value will be saved as a literal in the compiled function's definition, as if (QUOTE VALUE-OF-EXPRESSION) had appeared instead of (CONSTANT EXPRESSION).

If the value of X does not have a readable print name, then the expression X itself will be saved with the function, and it will be evaluated when the function is first loaded. The value will then be stored in the function's literals, and will be retrieved on future references.

If a user program needed a list of 30 NILs, the user could specify (CONSTANT (to 30 collect NIL)) instead of (QUOTE (NIL NIL ...)). The former is more concise and displays the important parameter much more directly than the latter.

CONSTANT can also be used to denote values that cannot be quoted directly, such as (CONSTANT (PACK NIL)), (CONSTANT (ARRAY 10)). It is also useful to parameterize quantities that are constant at run time but may differ at compile time, e.g., (CONSTANT BITSPERWORD) in a program is exactly equivalent to 36, if the variable BITSPERWORD is bound to 36 when the CONSTANT expression is evaluated at compile time.

Whereas the function CONSTANT attempts to evaluate the expression as soon as possible (compile-time, load-time, or

first-run-time), other options are available, using the following two function:

#### (LOADTIMECONSTANT X)

[Function]

Similar to CONSTANT, except that the evaluation of X is deferred until the compiled code for the containing function is loaded in. For example, (LOADTIMECONSTANT (DATE)) will return the date the code was loaded. If LOADTIMECONSTANT is interpreted, it merely returns the value of X.

#### (DEFERREDCONSTANT X)

[Function]

Similar to **CONSTANT**, except that the evaluation of *X* is always deferred until the compiled function is first run. This is useful when the storage for the constant is excessive so that it shouldn't be allocated until (unless) the function is actually invoked. If **DEFERREDCONSTANT** is interpreted, it merely returns the value of *X*.

# (CONSTANTS VAR<sub>1</sub> VAR<sub>2</sub> ... VAR<sub>N</sub>)

[NLambda NoSpread Function]

Defines  $VAR_1$ , ...  $VAR_N$  (unevaluated) to be compile-time constants. Whenever the compiler encounters a (free) reference to one of these constants, it will compile the form (CONSTANT  $VAR_i$ ) instead.

If  $VAR_i$  is a list of the form ( $VAR\ FORM$ ), a free reference to the variable will compile as (CONSTANT FORM).

The compiler prints a warning if user code attempts to bind a variable previously declared as a constant.

Constants can be saved using the CONSTANTS file package command (page 17.37).

# 18.5 Compiling Function Calls

When compiling the call to a function, the compiler must know the type of the function, to determine how the arguments should be prepared (evaluated/unevaluated, spread/nospread). There are three seperate cases: lambda, nlambda spread, and nlambda nospread functions.

To determine which of these three cases is appropriate, the compiler will first look for a definition among the functions in the file that is being compiled. The function can be defined anywhere in any of the files given as arguments to BCOMPL, TCOMPL, BRECOMPILE or RECOMPILE. If the function is not contained in the file, the compiler will look for other

information in the variables NLAMA, NLAML, and LAMS, which can be set by the user:

# 

# LAMS [Variable]

A list of functions to be treated as lambda functions by the compiler. Note that including functions on LAMS is only necessary to override in-core nlambda definitions, since in the absence of other information, the compiler assumes the function is a lambda.

If the function is not contained in a-file, or on the lists NLAMA, NLAML, or LAMS, the compiler will look for a current definition in the Interlisp system, and use its type. If there is no current definition, next COMPILEUSERFN is called:

#### COMPILEUSERFN

[Variable]

When compiling a function call, if the function type cannot be found by looking in files, the variables NLAMA, NLAML, or LAMS, or at a current definition, then if the value of COMPILEUSERFN is not NIL, the compiler calls (the value of) COMPILEUSERFN giving it as arguments CDR of the form and the form itself, i.e., the compiler does (APPLY\* COMPILEUSERFN (CDR FORM) FORM). If a non-NIL value is returned, it is compiled instead of FORM. If NIL is returned, the compiler compiles the original expression as a call to a lambda spread that is not yet defined.

Note that **COMPILEUSERFN** is only called when the compiler encounters a *list* **CAR** of which is not the name of a defined function. The user can instruct the compiler about how to compile other data types via **COMPILETYPELST**, page 18.11.

CLISP uses **COMPILEUSERFN** to tell the compiler how to compile iterative statements, **IF-THEN-ELSE** statements, and pattern match constructs (See page 18.11).

If the compiler cannot determine the function type by any of the means above, it assumes that the function is a lambda function, and its arguments are to be evaluated.

If there are nlambda functions called from the functions being compiled, and they are only defined in a separate file, they must be included on **NLAMA** or **NLAML**, or the compiler will incorrectly assume that their arguments are to be evaluated, and compile the calling function correspondingly. Note that this is only necessary if the compiler does not "know" about the function. If the function is defined at compile time, or is handled via a macro, or is contained in the same group of files as the functions that call it, the compiler will automatically handle calls to that function correctly.

# 18.6 FUNCTION and Functional Arguments

Compiling the function FUNCTION (page 10.18) may involve creating and compiling a seperate "auxiliary function", which will be called at run time. An auxiliary function is named by attaching a GENSYM (page 2.10) to the end of the name of the function in which they appear, e.g., FOOA0003. For example, suppose FOO is defined as (LAMBDA (X) ... (FOO1 X (FUNCTION ...)) ...) and compiled. When FOO is run, FOO1 will be called with two arguments, X, and FOOA000N and FOO1 will call FOOA000N each time it uses its functional argument.

Compiling **FUNCTION** will *not* create an auxiliary function if it is a functional argument to a function that compiles open, such as most of the mapping functions (**MAPCAR**, **MAPLIST**, etc.). Note that a considerable savings in time could be achieved by making **FOO1** compile open via a computed macro (page 10.21), e.g.

DEF is the definition of FOO1 as a function of just its first argument, and FN is the name used for its functional argument in its definition. In this case, (FOO1 X (FUNCTION ...)) would compile as an expression, containing the argument to FUNCTION as an open LAMBDA expression. Thus you save not only the function call to FOO1, but also each of the function calls to its functional argument. For example, if FOO1 operates on a list of length ten, eleven function calls will be saved. Of course, this savings in time costs space, and the user must decide which is more important.

## 18.7 Open Functions

When a function is called from a compiled function, a system routine is invoked that sets up the parameter and control push lists as necessary for variable bindings and return information. If the amount of time spent *inside* the function is small, this function calling time will be a significant percentage of the total time required to use the function. Therefore, many "small" functions, e.g., CAR, CDR, EQ, NOT, CONS are always compiled "open", i.e., they do not result in a function call. Other larger functions such as PROG, SELECTQ, MAPC, etc. are compiled open because they are frequently used. The user can make other functions compile open via MACRO definitions (see page 10.21). The user can also affect the compiled code via COMPILEUSERFN (page 18.9) and COMPILETYPELST (page 18.11).

## 18.8 COMPILETYPELST

Most of the compiler's mechanism deals with how to handle forms (lists) and variables (literal atoms). The user can affect the compiler's behaviour with respect to lists and literal atoms in a number of ways, e.g. macros, declarations, **COMPILEUSERFN** (page 18.9), etc. **COMPILETYPELST** allows the user to tell the compiler what to do when it encounters a data type other than a list or an atom. It is the facility in the compiler that corresponds to **DEFEVAL** (page 10.13) for the interpreter.

### **COMPILETYPELST**

[Variable]

A list of elements of the form (TYPENAME . FUNCTION). Whenever the compiler encounters a datum that is not a list and not an atom (or a number) in a context where the datum is being evaluated, the type name of the datum is looked up on COMPILETYPELST. If an entry appears CAR of which is equal to the type name, CDR of that entry is applied to the datum. If the value returned by this application is not EQ to the datum, then that value is compiled instead. If the value is EQ to the datum, or if there is no entry on COMPILETYPELST for this type name, the compiler simply compiles the datum as (QUOTE DATUM).

## 18.9 Compiling CLISP

Since the compiler does not know about CLISP, in order to compile functions containing CLISP constructs, the definitions

must first be **DWIMIFY**ed (page 21.18). The user can automate this process in several ways:

- (1) If the variable **DWIMIFYCOMPFLG** is **T**, the compiler will always **DWIMIFY** expressions before compiling them. **DWIMIFYCOMPFLG** is initially **NIL**.
- (2) If a file has the property FILETYPE with value CLISP on its property list, TCOMPL, BCOMPL, RECOMPILE, and BRECOMPILE will operate as though DWIMIFYCOMPFLG is T and DWIMIFY all expressions before compiling.
- (3) If the function definition has a local CLISP declaration (see page 21.13), including a null declaration, i.e., just (CLISP:), the definition will be automatically DWIMIFYed before compiling.

Note: COMPILEUSERFN (page 18.9) is defined to call DWIMIFY on iterative statements, IF-THEN statements, and fetch, replace, and match expressions, i.e., any CLISP construct which can be recognized by its CAR of form. Thus, if the only CLISP constructs in a function appear inside of iterative statements, IF statements, etc., the function does not have to be dwimified before compiling.

If **DWIMIFY** is ever unsuccessful in processing a **CLISP** expression, it will print the error message **UNABLE TO DWIMIFY** followed by the expression, and go into a break unless **DWIMESSGAG** = **T**. In this case, the expression is just compiled as is, i.e. as though CLISP had not been enabled. The user can exit the break in several different ways: (1) type **OK** to the break, which will cause the compiler to try again, e.g. the user could define some missing records while in the break, and then continue; or (2) type \(\frac{1}{2}\), which will cause the compiler to simply compile the expression as is, i.e. as though CLISP had not been enabled in the first place; or (3) return an expression to be compiled in its place by using the **RETURN** break command (page 14.6).

Note: TCOMPL, BCOMPL, RECOMPILE, and BRECOMPILE all scan the entire file before doing any compiling, and take note of the names of all functions that are defined in the file as well as the names of all variables that are set by adding them to NOFIXFNSLST and NOFIXVARSLST, respectively. Thus, if a function is not currently defined, but is defined in the file being compiled, when DWIMIFY is called before compiling, it will not attempt to interpret the function name as CLISP when it appears as CAR of a form. DWIMIFY also takes into account variables that have been declared to be LOCALVARS, or SPECVARS, either via block declarations or DECLARE expressions in the function being compiled, and does not attempt spelling correction on these variables. The declaration USEDFREE may also be used to declare variables simply used freely in a function. These variables will also be left alone by DWIMIFY. Finally, NOSPELLFLG (page 20.13) is reset to **T** when compiling functions from a file (as opposed to

18.12

from their in-core definition) so as to suppress spelling correction.

## 18.10 Compiler Functions

Normally, the compiler is envoked through file package commands that keep track of the state of functions, and manage a set of files, such as MAKEFILE (page 17.10). However, it is also possible to explicitly call the compiler using one of a number of functions. Functions may be compiled from in-core definitions (via COMPILE), or from definitions in files (TCOMPL), or from a combination of in-core and file definitions (RECOMPILE).

TCOMPL and RECOMPILE produce "compiled" files. Compiled files usually have the same name as the symbolic file they were made from, suffixed with DCOM (the compiled file extension is stored as the value of the variable COMPILE.EXT). The file name is constructed from the name field only, e.g., (TCOMPL '<BOBROW>FOO.TEM;3) produces FOO.DCOM on the connected directory. The version number will be the standard default.

A "compiled file" contains the same expressions as the original symbolic file, except that (1) a special FILECREATED expression appears at the front of the file which contains information used by the file package, and which causes the message COMPILED **ON** DATE to be printed when the file is loaded (the actual string printed is the value of COMPILEHEADER); (2) every DEFINEQ in the symbolic file is replaced by the corresponding compiled definitions in the compiled file; and (3) expressions following a **DONTCOPY** tag inside of a **DECLARE**: (page 17.40) that appears in the symbolic file are not copied to the compiled file. The compiled definitions appear at the front of the compiled file, i.e., before the other expressions in the symbolic file, regardless of where they appear in the symbolic file. The only exceptions are expressions that follow a FIRST tag inside of a DECLARE: (page 17.40). This "compiled" file can be loaded into any Interlisp system with LOAD (page 17.6).

Note: When a function is compiled from its in-core definition (as opposed to being compiled from a definition in a file), and the function has been modified by BREAK, TRACE, BREAKIN, or ADVISE, it is first restored to its original state, and a message is printed out, e.g., FOO UNBROKEN. If the function is not defined by an expr definition, the value of the function's EXPR property is used for the compilation, if there is one. If there is no EXPR property, and the compilation is being performed by RECOMPILE, the definition of the function is obtained from the

file (using LOADFNS). Otherwise, the compiler prints (FN NOT COMPILEABLE), and goes on to the next function.

### (COMPILE X FLG)

[Function]

X is a list of functions (if atomic, (LIST X) is used). **COMPILE** first asks the standard compiler questions (page 18.1), and then compiles each function on X, using its in-core definition. Returns X.

If compiled definitions are being written to a file, the file is closed unless FLG = T.

### (COMPILE1 FN DEF —)

[Function]

Compiles *DEF*, redefining *FN* if STRF = T (STRF is one of the variables set by COMPSET, page 18.1). COMPILE1 is used by COMPILE, TCOMPL, and RECOMPILE.

If **DWIMIFYCOMPFLG** is **T**, or *DEF* contains a CLISP declaration, *DEF* is dwimified before compiling. See page 18.11.

### (TCOMPL FILES)

[Function]

TCOMPL is used to "compile files"; given a symbolic LOAD file (e.g., one created by MAKEFILE), it produces a "compiled file". FILES is a list of symbolic files to be compiled (if atomic, (LIST FILES) is used). TCOMPL asks the standard compiler questions (page 18.1), except for "OUTPUT FILE:". The output from the compilation of each symbolic file is written on a file of the same name suffixed with DCOM, e.g., (TCOMPL '(SYM1 SYM2)) produces two files, SYM1.DCOM and SYM2.DCOM.

TCOMPL processes the files one at a time, reading in the entire file. For each FILECREATED expression, the list of functions that were marked as changed by the file package is noted, and the FILECREATED expression is written onto the output file. For each DEFINEQ expression, TCOMPL adds any nlambda functions defined in the DEFINEQ to NLAMA or NLAML, and adds lambda functions to LAMS, so that calls to these functions will be compiled correctly (see page 18.9). NLAMA, NLAML, and LAMS are rebound to their top level values (using RESETVAR) by all of the compiling functions, so that any additions to these lists while inside of these functions will not propagate outside. Expressions beginning with DECLARE: are processed specially (see page 17.40). All other expressions are collected to be subsequently written onto the output file.

After processing the file in this fashion, TCOMPL compiles each function, except for those functions which appear on the list DONTCOMPILEFNS (initially NIL), and writes the compiled definition onto the output file. TCOMPL then writes onto the output file the other expressions found in the symbolic file.

**DONTCOMPILEFNS** might be used for functions that compile open, since their definitions would be superfluous when operating with the compiled file. Note that **DONTCOMPILEFNS** can be set via block declarations (see page 18.17).

Note: If the rootname of a file has the property FILETYPE with value CLISP, or value a list containing CLISP, TCOMPL rebinds DWIMIFYCOMPFLG to T while compiling the functions on FILE, so the compiler will DWIMIFY all expressions before compiling them. See page 18.11.

**TCOMPL** returns a list of the names of the output files. All files are properly terminated and closed. If the compilation of any file is aborted via an error or control-D, all files are properly closed, and the (partially complete) compiled file is deleted.

### (RECOMPILE PFILE CFILE FNS)

[Function]

The purpose of **RECOMPILE** is to allow the user to update a compiled file without recompiling every function in the file. **RECOMPILE** does this by using the results of a previous compilation. It produces a compiled file similar to one that would have been produced by **TCOMPL**, but at a considerable savings in time by only compiling selected functions, and copying the compiled definitions for the remainder of the functions in the file from an earlier **TCOMPL** or **RECOMPILE** file.

**PFILE** is the name of the **Pretty** file (source file) to be compiled; **CFILE** is the name of the **Compiled** file containing compiled definitions that may be copied. **FNS** indicates which functions in **PFILE** are to be recompiled, e.g., have been changed or defined for the first time since **CFILE** was made. Note that **PFILE**, not **FNS**, drives **RECOMPILE**.

RECOMPILE asks the standard compiler questions (page 18.1), except for "OUTPUT FILE:". As with TCOMPL, the output automatically goes to PFILE.DCOM. RECOMPILE processes PFILE the same as does TCOMPL except that DEFINEQ expressions are not actually read into core. Instead, RECOMPILE uses the filemap (page 17.55) to obtain a list of the functions contained in PFILE. The filemap enables RECOMPILE to skip over the DEFINEQs in the file by simply resetting the file pointer, so that in most cases the scan of the symbolic file is very fast (the only processing required is the reading of the non-DEFINEQs and the processing of the DECLARE: expressions as with TCOMPL). A map is built if the symbolic file does not already contain one, for example if it was written in an earlier system, or with BUILDMAPFLG = NIL (page 17.56).

After this initial scan of *PFILE*, **RECOMPILE** then processes the functions defined in the file. For each function in *PFILE*, **RECOMPILE** determines whether or not the function is to be (re)compiled. Functions that are members of **DONTCOMPILEFNS** 

are simply ignored. Otherwise, a function is recompiled if (1) FNS is a list and the function is a member of that list; or (2) FNS = T or EXPRS and the function is defined by an expr definition; or (3) FNS = CHANGES and the function is marked as having been changed in the FILECREATED expression in PFILE; or (4) FNS = ALL. If a function is not to be recompiled, RECOMPILE obtains its compiled definition from CFILE, and copies it (and all generated subfunctions) to the output file, PFILE.DCOM. If the function does not appear on CFILE, RECOMPILE simply recompiles it. Finally, after processing all functions, RECOMPILE writes out all other expressions that were collected in the prescan of PFILE.

Note: If FNS = ALL, CFILE is superfluous, and does not have to be specified. This option may be used to compile a symbolic file that has never been compiled before, but which has already been loaded (since using TCOMPL would require reading the file in a second time).

If CFILE = NIL, PFILE.DCOM (the old version of the output file) is used for copying from. If both FNS and CFILE are NIL, FNS is set to the value of RECOMPILEDEFAULT, which is initially CHANGES. Thus the user can perform his edits, dump the file, and then simply (RECOMPILE 'FILE) to update the compiled file.

The value of **RECOMPILE** is the file name of the new compiled file, *PFILE*.**DCOM**. If **RECOMPILE** is aborted due to an error or control-D, the new (partially complete) compiled file will be closed and deleted.

**RECOMPILE** is designed to allow the user to conveniently and efficiently update a compiled file, even when the corresponding symbolic file has not been (completely) loaded. For example, the user can perform a **LOADFROM** (page 17.8) to "notice" a symbolic file, edit the functions he wants to change (the editor will automatically load those functions not already loaded), call **MAKEFILE** (page 17.10) to update the symbolic file (**MAKEFILE** will copy the unchanged functions from the old symbolic file), and then perform (**RECOMPILE** *PFILE*).

Note: Since PRETTYDEF automatically outputs a suitable DECLARE: expression to indicate which functions in the file (if any) are defined as NLAMBDAs, calls to these functions will be handled correctly, even though the NLAMBDA functions themselves may never be loaded, or even looked at, by RECOMPILE.

18.16

## 18.11 Block Compiling

In Interlisp-10, block compiling provides a way of compiling several functions into a single block. Function calls between the component functions of the block are very fast. Thus, compiling a block consisting of just a single recursive function may be yield great savings if the function calls itself many times. The output of a block compilation is a single, usually large, function. Calls from within the block to functions outside of the block look like regular function calls. A block can be entered via several different functions, called entries. These must be specified when the block is compiled.

In Interlisp-D, block compiling is handled somewhat differently; block compiling provides a mechanism for hiding function names internal to a block, but it does not provide a performance improvement. Block compiling in Interlisp-D works by automatically renaming the block functions with special names, and calling these functions with the normal function-calling mechanisms. Specifically, a function FN is renamed to \BLOCK-NAME/FN. For example, function FOO in block BAR is renamed to "\BAR/FOO". Note that it is possible with this scheme to break functions internal to a block.

## 18.11.1 Block Declarations

Block compiling a file frequently involves giving the compiler a lot of information about the nature and structure of the compilation, e.g., block functions, entries, specvars, etc. To help with this, there is the **BLOCKS** file package command (page 17.42), which has the form:

(BLOCKS BLOCK 1 BLOCK 2 ... BLOCK N)

where each  $BLOCK_i$  is a block declaration. The **BLOCKS** command outputs a **DECLARE**: expression, which is noticed by **BCOMPL** and **BRECOMPILE**. **BCOMPL** and **BRECOMPILE** are sensitive to these declarations and take the appropriate action.

Note: Masterscope (page 19.1) includes a facility for checking the block declarations of a file or files for various anomalous conditions, e.g. functions in block declarations which aren't on the file(s), functions in ENTRIES not in the block, variables that may not need to be SPECVARS because they are not used freely below the places they are bound, etc.

A block declaration is a list of the form:

(BLKNAME BLKFN<sub>1</sub> ... BLKFN<sub>M</sub> ( $VAR_1 \cdot VALUE_1$ ) ... ( $VAR_N \cdot VALUE_N$ ))

 $\it BLKNAME$  is the name of a block.  $\it BLKFN_1$  ...  $\it BLKFN_M$  are the functions in the block and correspond to  $\it BLKFNS$  in the call to

**BLOCKCOMPILE.** The  $(VAR_i \cdot VALUE_i)$  expressions indicate the settings for variables affecting the compilation of that block. If  $VALUE_i$  is atomic, then  $VAR_i$  is set to  $VALUE_i$ , otherwise  $VAR_i$  is set to the **UNION** (page 3.11) of  $VALUE_i$  and the current value of the variable  $VAR_i$ . Also, expressions of the form (VAR \* FORM) will cause FORM to be evaluated and the resulting list used as described above (e.g. (GLOBALVARS \* MYGLOBALVARS)).

For example, consider the block declaration below. The block name is EDITBLOCK, it includes a number of functions (EDITLO, EDITL1, ... EDITH), and it sets the variables ENTRIES, SPECVARS, RETFNS, and GLOBALVARS.

### (EDITBLOCK

EDITLO EDITL1 UNDOEDITL EDITCOM EDITCOMA
EDITMAC EDITCOMS EDIT]UNDO UNDOEDITCOM EDITH
(ENTRIES EDITLO ## UNDOEDITL)
(SPECVARS L COM LCFLG #1 #2 #3 LISPXBUFS)
(RETFNS EDITLO)
(GLOBALVARS EDITCOMSA EDITCOMSL EDITOPS))

Whenever BCOMPL or BRECOMPILE encounter a block declaration, they rebind RETFNS, SPECVARS, GLOBALVARS, BLKLIBRARY, and DONTCOMPILEFNS to their top level values, bind BLKAPPLYFNS and ENTRIES to NIL, and bind BLKNAME to the first element of the declaration. They then scan the rest of the declaration, setting these variables as described above. When the declaration is exhausted, the block compiler is called and given BLKNAME, the list of block functions, and ENTRIES.

If a function appears in a block declaration, but is not defined in one of the files, then if it has an in-core definition, this definition is used and a message printed NOT ON FILE, COMPILING IN CORE DEFINITION. Otherwise, the message NOT COMPILEABLE, is printed and the block declaration processed as though the function were not on it, i.e. calls to the function will be compiled as external function calls.

Note that since all compiler variables are rebound for each block declaration, the declaration only has to set those variables it wants *changed*. Furthermore, setting a variable in one declaration has no effect on the variable's value for another declaration.

After finishing all blocks, **BCOMPL** and **BRECOMPILE** treat any functions in the file that did not appear in a block declaration in the same way as do **TCOMPL** and **RECOMPILE**. If the user wishes a function compiled separately as well as in a block, or if he wishes to compile some functions (not blockcompile), with some compiler variables changed, he can use a special pseudo-block declaration of the form

(NIL BLKFN<sub>1</sub> ... BLKFN<sub>M</sub> (VAR<sub>1</sub> . VALUE<sub>1</sub>) ... (VAR<sub>N</sub> . VALUE<sub>N</sub>))

18.18 COMPILER

which means that  $BLKFN_1$  ...  $BLKFN_M$  should be compiled after first setting  $VAR_1$  ...  $VAR_N$  as described above.

The following variables control other aspects of compiling a block:

### RETFNS

[Variable]

Value is a list of internal block functions whose names must appear on the stack, e.g., if the function is to be returned from **RETFROM**, **RETTO**, **RETEVAL**, etc. Usually, internal calls between functions in a block are not put on the stack.

### **BLKAPPLYFNS**

[Variable]

Value is a list of internal block functions called by other functions in the same block using **BLKAPPLY** or **BLKAPPLY\*** for efficiency reasons.

Normally, a call to APPLY from inside a block would be the same as a call to any other function outside of the block. If the first argument to APPLY turned out to be one of the entries to the block, the block would have to be reentered. BLKAPPLYFNS enables a program to compute the name of a function in the block to be called next, without the overhead of leaving the block and reentering it. This is done by including on the list BLKAPPLYFNS those functions which will be called in this fashion, and by using BLKAPPLY in place of APPLY, and BLKAPPLY\* in place of APPLY\*. If BLKAPPLY or BLKAPPLY\* is given a function not on BLKAPPLYFNS, the effect is the same as a call to APPLY or APPLY\* and no error is generated. Note however, that BLKAPPLYFNS must be set at compile time, not run time, and furthermore, that all functions on BLKAPPLYFNS must be in the block, or an error is generated (at compile time), NOT ON BLKFNS.

### **BLKAPPLYFNS**

[Variable]

Value is a list of functions that are considered to be in the "block library" of functions that should automatically be included in the block if they are called within the block.

Compiling a function open via a macro provides a way of eliminating a function call. For block compiling, the same effect can be achieved by including the function in the block. A further advantage is that the code for this function will appear only once in the block, whereas when a function is compiled open, its code appears at each place where it is called.

The block library feature provides a convenient way of including functions in a block. It is just a convenience since the user can always achieve the same effect by specifying the function(s) in question as one of the block functions, provided it has an expr

definition at compile time. The block library feature simply eliminates the burden of supplying this definition.

To use the block library feature, place the names of the functions of interest on the list BLKLIBRARY, and their expr definitions on the property list of the functions under the property BLKLIBRARYDEF. When the block compiler compiles a form, it first checks to see if the function being called is one of the block functions. If not, and the function is on BLKLIBRARY, its definition is obtained from the property value of BLKLIBRARYDEF, and it is automatically included as part of the block.

## 18.11.2 Block Compiling Functions

There are three user level functions for block compiling, BLOCKCOMPILE, BCOMPL, and BRECOMPILE, corresponding to COMPILE, TCOMPL, and RECOMPILE. Note that all of the remarks on macros, globalvars, compiler messages, etc., all apply equally for block compiling. Using block declarations, the user can intermix in a single file functions compiled normally and block compiled functions.

### (BLOCKCOMPILE BLKNAME BLKFNS ENTRIES FLG)

[Function]

BLKNAME is the name of a block, BLKFNS is a list of the functions comprising the block, and ENTRIES a list of entries to the block.

Each of the entries must also be on *BLKFNS* or an error is generated, **NOT ON BLKFNS**. If only one entry is specified, the block name can also be one of the *BLKFNS*, e.g., (**BLOCKCOMPILE** 'FOO '(FOO FIE FUM) '(FOO)). However, if more than one entry is specified, an error will be generated, **CAN'T BE BOTH AN ENTRY AND THE BLOCK NAME**.

If ENTRIES is NIL, (LIST BLKNAME) is used, e.g., (BLOCKCOMPILE 'COUNT'(COUNT COUNT1))

If BLKFNS is NIL, (LIST BLKNAME) is used, e.g., (BLOCKCOMPILE 'EQUAL)

**BLOCKCOMPILE** asks the standard compiler questions (page 18.1), and then begins compiling. As with **COMPILE**, if the compiled code is being written to a file, the file is closed unless *FLG* = T. The value of **BLOCKCOMPILE** is a list of the entries, or if *ENTRIES* = **NIL**, the value is *BLKNAME*.

The output of a call to **BLOCKCOMPILE** is one function definition for *BLKNAME*, plus definitions for each of the functions on *ENTRIES* if any. These entry functions are very short functions which immediately call *BLKNAME*.

18.20

### (BCOMPL FILES CFILE — —)

[Function]

FILES is a list of symbolic files (if atomic, (LIST FILES) is used). BCOMPL differs from TCOMPL in that it compiles all of the files at once, instead of one at a time, in order to permit one block to contain functions in several files. (If you have several files to be BCOMPLed separately, you must make several calls to BCOMPL.) Output is to CFILE if given, otherwise to a file whose name is (CAR FILES) suffixed with DCOM. For example, (BCOMPL '(EDIT WEDIT)) produces one file, EDIT.DCOM.

**BCOMPL** asks the standard compiler questions (page 18.1), except for "OUTPUT FILE:", then processes each file exactly the same as TCOMPL (page 18.14). BCOMPL next processes the block declarations as described above. Finally, it compiles those functions not mentioned in one of the block declarations, and then writes out all other expressions.

If any of the files have property FILETYPE with value CLISP, or a list containing CLISP, then DWIMIFYCOMPFLG is rebound to T for all of the files. See page 18.11.

The value of **BCOMPL** is the output file (the new compiled file). If the compilation is aborted due to an error or control-D, all files are closed and the (partially complete) output file is deleted.

Note that it is permissible to TCOMPL files set up for BCOMPL; the block declarations will simply have no effect. Similarly, you can BCOMPL a file that does not contain any block declarations and the result will be the same as having TCOMPLed it.

### (BRECOMPILE FILES CFILE FNS —)

[Function]

**BRECOMPILE** plays the same role for **BCOMPL** that **RECOMPILE** plays for **TCOMPL**. Its purpose is to allow the user to update a compiled file without requiring an entire **BCOMPL**.

FILES is a list of symbolic files (if atomic, (LIST FILES) is used). CFILE is the compiled file produced by BCOMPL or a previous BRECOMPILE that contains compiled definitions that may be copied. The interpretation of FNS is the same as with RECOMPILE.

**BRECOMPILE** asks the standard compiler questions (page 18.1), except for "OUTPUT FILE:". As with BCOMPL, output automatically goes to FILE.DCOM, where FILE is the first file in FILES.

BRECOMPILE processes each file the same as RECOMPILE (page 18.15), then processes each block declaration. If any of the functions in the block are to be recompiled, the entire block must be (is) recompiled. Otherwise, the block is copied from CFILE as with RECOMPILE. For pseudo-block declarations of the form (NIL FN1 ...), all variable assignments are made, but only those functions indicated by FNS are recompiled.

After completing the block declarations, **BRECOMPILE** processes all functions that do not appear in a block declaration, recompiling those dictated by *FNS*, and copying the compiled definitions of the remaining from *CFILE*.

Finally, **BRECOMPILE** writes onto the output file the "other expressions" collected in the initial scan of *FILES*.

The value of **BRECOMPILE** is the output file (the new compiled file). If the compilation is aborted due to an error or control-D, all files are closed and the (partially complete) output file is deleted.

If CFILE = NIL, the old version of FILE.DCOM is used, as with RECOMPILE. In addition, if FNS and CFILE are both NIL, FNS is set to the value of RECOMPILEDEFAULT, initially CHANGES.

## 18.12 Compiler Error Messages

Messages describing errors in the function being compiled are also printed on the terminal. These messages are always preceded by \*\*\*\*\*. Unless otherwise indicated below, the compilation will continue.

### (FN NOT ON FILE, COMPILING IN CORE DEFINITION)

From calls to BCOMPL and BRECOMPILE.

### (FN NOT COMPILEABLE)

An EXPR definition for FN could not be found. In this case, no code is produced for FN, and the compiler proceeds to the next function to be compiled, if any.

### (FN NOT FOUND)

Occurs when **RECOMPILE** or **BRECOMPILE** try to copy the compiled definition of *FN* from *CFILE*, and cannot find it. In this case, no code is copied and the compiler proceeds to the next function to be compiled, if any.

### (FN NOT ON BLKFNS)

FN was specified as an entry to a block, or else was on BLKAPPLYFNS, but did not appear on the BLKFNS. In this case, no code is produced for the entire block and the compiler proceeds to the next function to be compiled, if any.

### (FN CAN'T BE BOTH AN ENTRY AND THE BLOCK NAME)

In this case, no code is produced for the entire block and the compiler proceeds to the next function to be compiled, if any.

## (BLKNAME - USED BLKAPPLY WHEN NOT APPLICABLE)

**BLKAPPLY** is used in the block *BLKNAME*, but there are no **BLKAPPLYFNS** or **ENTRIES** declared for the block.

### (VAR SHOULD BE A SPECVAR - USED FREELY BY FN)

While compiling a block, the compiler has already generated code to bind VAR as a LOCALVAR, but now discovers that FN uses

VAR freely. VAR should be declared a SPECVAR and the block

recompiled.

((\* --) COMMENT USED FOR VALUE) A comment appears in a context where its value is being used,

> e.g. (LIST X (\* --) Y). The compiled function will run, but the value at the point where the comment was used is undefined.

((FORM) - NON-ATOMIC CAR OF FORM) If user intended to treat the value of FORM as a function, he

should use APPLY\* (page 10.12). FORM is compiled as if APPLY\*

had been used.

((SETQ VAR EXPR --) BAD SETQ) **SETQ** of more than two arguments.

(FN - USED AS ARG TO NUMBER FN?) The value of a predicate, such as GREATERP or EQ, is used as an

argument to a function that expects numbers, such as IPLUS.

(FN - NO LONGER INTERPRETED AS FUNCTIONAL ARGUMENT)

The compiler has assumed FN is the name of a function. If the user intended to treat the value of FN as a function, APPLY\* (page 10.12) should be used. This message is printed when FN is not defined, and is also a local variable of the function being compiled.

(FN - ILLEGAL RETURN) **RETURN** encountered when not in **PROG**.

(TG - ILLEGAL GO) GO encountered when not in a PROG.

(TG - MULTIPLY DEFINED TAG) TG is a PROG label that is defined more than once in a single

**PROG**. The second definition is ignored.

(TG - UNDEFINED TAG) TG is a PROG label that is referenced but not defined in a PROG.

(VAR - NOT A BINDABLE VARIABLE) VAR is NIL, T, or else not a literal atom.

(VAR VAL -- BAD PROG BINDING) Occurs when there is a prog binding of the form (VAR VAL<sub>1</sub> ...

 $VAL_N$ ).

(TG - MULTIPLY DEFINED TAG, LAP) TG is a label that was encountered twice during the second pass

> of the compilation. If this error occurs with no indication of a multiply defined tag during pass one, the tag is in a LAP macro.

(TG - UNDEFINED TAG, LAP) TG is a label that is referenced during the second pass of

compilation and is not defined. LAP treats TG as though it were

a COREVAL, and continues the compilation.

(TG - MULTIPLY DEFINED TAG, ASSEMBLE) TG is a label that is defined more than once in an assemble form.

(TG - UNDEFINED TAG, ASSEMBLE) TG is a label that is referenced but not defined in an assemble

(OP - OPCODE? - ASSEMBLE) OP appears as CAR of an assemble statement, and is illegal.

(NO BINARY CODE GENERATED OR LOADED FOR FN)

A previous error condition was sufficiently serious that binary

code for FN cannot be loaded without causing an error.

TOC.2 TABLE OF CONTENTS

Masterscope is an interactive program for analyzing and cross referencing user programs. It contains facilities for analyzing user functions to determine what other functions are called, how and where variables are bound, set, or referenced, as well as which functions use particular record declarations. Masterscope is able to analyze definitions directly from a file as well as in-core definitions.

Masterscope maintains a database of the results of the analyses it performs. Via a simple command language, the user may interrogate the database, call the editor on those expressions in functions that were analyzed which use variables or functions in a particular way, or display the tree structure of function calls among any set of functions.

Masterscope is interfaced with the editor and file package so that when a function is edited or a new definition loaded in, Masterscope knows that it must re-analyze that function.

The following sample session illustrates some of these facilities.

### 50←. ANALYZE FUNCTIONS ON RECORD

### NIL

51←. WHO CALLS RECFIELDLOOK (RECFIELDLOOK ACCESSDEF ACCESSDEF2 EDITREC) 52←. EDIT WHERE ANY CALL RECFIELDLOOK

RECORDWORD -- /RPLACA

RECORD1 -- /RPLACA, /SETTOPVAL

EDITREC -- /SETTOPVAL

### Statement 50

The user directs that the functions on file RECORD be analyzed. The leading period and space specify that this line is a Masterscope command. The user may also call Masterscope directly by typing (MASTERSCOPE). Masterscope prints a greeting and prompts with "\(-.\)". Within the top-level executive of Masterscope, the user may issue Masterscope commands, programmer's assistant commands, (e.g., REDO, FIX), or run programs. The user can exit from the Masterscope executive by typing OK. The function . is defined as a nlambda nospread function which interprets its argument as a Masterscope command, executes the command and returns.

Masterscope prints a . whenever it (re)analyzes a function, to let the user know what it is happening. The feedback when Masterscope analyzes a function is controlled by the flag MSPRINTFLG: if MSPRINTFLG is the atom ".", Masterscope will print out a period. (If an error in the function is detected, "?" is printed instead.) If MSPRINTFLG is a number N, Masterscope will print the name of the function it is analyzing every Nth function. If MSPRINTFLG is NIL, Masterscope won't print anything. Initial setting is ".". Note that the function name is printed when Masterscope starts analyzing, and the comma is printed when it finishes.

### Statement 51

The user asks which functions call **RECFIELDLOOK**. Masterscope responds with the list.

- The user asks to edit the expressions where the function RECFIELDLOOK is called. Masterscope calls EDITF on the functions it had analyzed that call RECFIELDLOOK, directing the editor to the appropriate expressions. The user then edits some of those expressions. In this example, the teletype editor is used. If Dedit is enabled as the primary editor, it would be called to edit the appropriate functions (see page 16.1).
- Statement 53 Next the user asks which functions call ERROR. Since some of the functions in the database have been changed, Masterscope re-analyzes the changed definitions (and prints out .'s for each function it analyzes). Masterscope responds that EDITREC is the only analyzed function that calls ERROR.
- Statement 54 The user asks to see a map of the ways in which RECFIELDLOOK is called from ACCESSDEF. A tree structure of the calls is displayed.
- Statement 55 The user then asks to see which functions call which functions in the list /FNS. Masterscope responds with a structured printout of these relations.

## 19.1 Command Language

The user communicates with Masterscope using an English-like command language, e.g., WHO CALLS PRINT. With these commands, the user can direct that functions be analyzed, interrogate Masterscope's database, and perform other operations. The commands deal with sets of functions, variables, etc., and relations between them (e.g., call, bind). Sets correspond to English nouns, relations to verbs.

A set of atoms can be specified in a variety of ways, either explicitly, e.g., FUNCTIONS ON FIE specifies the atoms in (FILEFNSLST 'FIE), or implicitly, e.g., NOT CALLING Y, where the meaning must be determined in the context of the rest of the command. Such sets of atoms are the basic building blocks which the command language deals with.

Masterscope also deals with relations between sets. For example, the relation CALL relates functions and other functions; the relations BIND and USE FREELY relate functions and variables. These relations are what get stored in the Masterscope database when functions are analyzed. In addition, Masterscope "knows" about file package conventions; CONTAIN relates files and various types of objects (functions, variables).

Sets and relations are used (along with a few additional words) to form sentence-like commands. For example, the command WHO ON 'FOO USE 'X FREELY will print out the list of functions contained in the file FOO which use the variable X freely. The

MASTERSCOPE

command EDIT WHERE ANY CALLS 'ERROR will call EDITF on those functions which have previously been analyzed that directly call ERROR, pointing at each successive expression where the call to ERROR actually occurs.

### 19.1.1 Commands

The normal mode of communication with Masterscope is via "commands". These are sentences in the Masterscope command language which direct Masterscope to answer questions or perform various operations.

Note: any command may be followed by **OUTPUT** *FILENAME* to send output to the given file rather than the terminal, e.g. **WHO CALLS WHO OUTPUT CROSSREF**.

### ANALYZE SET

### [Masterscope Command]

Analyze the functions in SET (and any functions called by them) and include the information gathered in the database. Masterscope will not re-analyzing a function if it thinks it already has valid information about that function in its database. The user may use the command REANALYZE (below) to force re-analysis.

Note that whenever a function is referred to in a command as a "subject" of one of the relations, it is automatically analyzed; the user need not give an explicit ANALYZE command. Thus, WHO IN MYFNS CALLS FIE will automatically analyze the functions in MYFNS if they have not already been analyzed.

Note also that only expr definitions will be analyzed; that is, Masterscope will not analyze compiled code. If necessary, the definition will be **DWIMIFY**ed before analysis. If there is no in-core definition for a function (either in the function definition cell or an **EXPR** property), Masterscope will attempt to read in the definition from a file. Files which have been explicitly mentioned previously in some command are searched first. If the definition cannot be found on any of those files, Masterscope looks among the files on **FILELST** for a definition. If a function is found in this manner, Masterscope will print a message "(reading from *FILENAME*)". If no definition can be found at all, Masterscope will print a message "*FN* can't be analyzed". If the function previously was known, the message "*FN* disappeared!" is printed.

### **REANALYZE** SET

### [Masterscope Command]

Causes Masterscope to reanalyze the functions in *SET* (and any functions called by them) even if it thinks it already has valid information in its database. For example, this would be

necessary if the user had disabled or subverted the file package, e.g. performed PUTD's to change the definition of functions.

### **ERASE SET**

[Masterscope Command]

Erase all information about the functions in SET from the database. ERASE by itself clears the entire database.

### **SHOW PATHS PATHOPTIONS**

[Masterscope Command]

Displays a tree of function calls. This is described on page 19.15.

SET RELATION SET

[Masterscope Command]

SET IS SET

[Masterscope Command]

### SET ARE SET

[Masterscope Command]

This command has the same format as an English sentence with a subject (the first SET), a verb (the RELATION or IS or ARE), and an object (the second SET). Any of the SETs within the command may be preceded by the question determiners WHICH or WHO (or just WHO alone). For example, WHICH FUNCTIONS CALL X prints the list of functions that call the function X. RELATION may be one of the relation words in present tense (CALL, BIND, TEST, SMASH, etc.) or used as a passive (e.g., WHO IS CALLED BY WHO). Other variants are allowed, e.g. WHO DOES X CALL, IS FOO CALLED BY FIE, etc.

The interpretation of the command depends on the number of question elements present:

- (1) If there is no question element, the command is treated as an assertion and Masterscope returns either T or NIL, depending on whether that assertion is true. Thus, ANY IN MYFNS CALL HELP will print T if any function in MYFNS call the function HELP, and NIL otherwise.
- (2) If there is one question element, Masterscope returns the list of items for which the assertion would be true. For example MYFN BINDS WHO USED FREELY BY YOURFN prints the list of variables bound by MYFN which are also used freely by YOURFN.
- (3) If there are two question elements, Masterscope will print a doubly indexed list:

←. WHO CALLS WHO IN /FNS<sup>CT</sup>
RECORDSTATEMENT -- /RPLNODE
RECORDECL1 -- /NCONC, /RPLACD, /RPLNODE
RECREDECLARE1 -- /PUTHASH
UNCLISPTRAN -- /PUTHASH, /RPLNODE2
RECORDWORD -- /RPLACA
RECORD1 -- /RPLACA, /SETTOPVAL

MASTERSCOPE

### EDITREC -- /SETTOPVAL

### **EDIT WHERE SET RELATION SET [- EDITCOMS]**

[Masterscope Command]

(WHERE may be omitted.) The first SET refers to a set of functions. The EDIT command calls the editor on each expression where the RELATION actually occurs. For example, EDIT WHERE ANY CALL ERROR will call EDITF on each (analyzed) function which calls ERROR stopping within a TTY: at each call to ERROR. Currently one cannot EDIT WHERE a file which CONTAINS a datum, nor where one function CALLS another SOMEHOW.

EDITCOMS, if given, are a list of commands passed to EDITF to be performed at each expression. For example, EDIT WHERE ANY CALLS MYFN DIRECTLY - (SW 2 3) P will switch the first and second arguments to MYFN in every call to MYFN and print the result. EDIT WHERE ANY ON MYFILE CALL ANY NOT @ GETD will call the editor on any expression involving a call to an undefined function. Note that EDIT WHERE X SETS Y will point only at those expressions where Y is actually set, and will skip over places where Y is otherwise mentioned.

### SHOW WHERE SET RELATION SET

[Masterscope Command]

Like the EDIT command except merely prints out the expressions without calling the editor.

### **EDIT SET [- EDITCOMS]**

[Masterscope Command]

Calls EDITF on each function in SET. EDITCOMS, if given, will be passed as a list of editor commands to be executed. For example EDIT ANY CALLING FN1 - (R FN1 FN2) will replace FN1 by FN2 in those functions that call FN1.

### **DESCRIBE SET**

[Masterscope Command]

Prints out the BIND, USE FREELY and CALL information about the functions in *SET*. For example, the command **DESCRIBE PRINTARGS** might print out:

PRINTARGS[N,FLG]

binds: TEM.LST.X

calls: MSRECORDFILE, SPACES, PRIN1

called by: PRINTSENTENCE, MSHELP, CHECKER

This shows that PRINTARGS has two arguments, N and FLG, binds internally the variables TEM, LST and X, calls MSRECORDFILE, SPACES and PRIN1 and is called by PRINTSENTENCE, MSHELP, and CHECKER.

The user can specify additional information to be included in the description. **DESCRIBELST** is a list each of whose elements is a list containing a descriptive string and a form. The form is evaluated (it can refer to the name of the funtion being described by the

free variable FN); if it returns a non-NIL value, the description string is printed followed by the value. If the value is a list, its elements are printed with commas between them. For example, the entry ("types: " (GETRELATION FN '(USE TYPE) T) would include a listing of the types used by each function.

### CHECK SET

### [Masterscope Command]

Checks for various anomolous conditions (mainly in the compiler declarations) for the files in *SET* (if *SET* is not given, FILELST is used). For example, this command will warn about variables which are bound but never referenced, functions in **BLOCKS** delarations which aren't on the file containing the declaration, functions declared as **ENTRIES** but not in the block, variables which may not need to be declared **SPECVARS** because they are not used freely below the places where they are bound, etc.

### FOR VARIABLE SET I.S. TAIL

### [Masterscope Command]

This command provides a way of combining **CLISP** iterative statements with Masterscope. An iterative statement will be constructed in which *VARIABLE* is iteratively assigned to each element of *SET*, and then the iterative statement tail *I.S.TAIL* is executed. For example,

# FOR X CALLED BY FOO WHEN CCODEP DO (PRINTOUT T X ,,, (ARGLIST X) T)

will print out the name and argument list of all of the compiled functions which are called by **FOO**.

### 19.1.2 Relations

A relation is specified by one of the keywords below. Some of these "verbs" accept modifiers. For example, USE, SET, SMASH and REFERENCE all may be modified by FREELY. The modifier may occur anywhere within the command. If there is more than one verb, any modifier between two verbs is assumed to modify the first one. For example, in USING ANY FREELY OR SETTING X, the FREELY modifies USING but not SETTING; the entire phrase is interpreted as the set of all functions which either use any variable freely or set the variable X, whether or not X is set freely. Verbs can occur in the present tense (e.g., USE, CALLS, BINDS, USES) or as present or past participles (e.g., CALLING, BOUND, TESTED). The relations (with their modifiers) recognized by Masterscope are:

### CALL

### [Masterscope Relation]

Function F1 calls F2 if the definition of F1 contains a form (F2 --). The CALL relation also includes any instance where a function

	uses a name as a function, as in (APPLY (QUOTE F2)) (FUNCTION F2), etc.	
CALL SOMEHOW	[Masterscope Relation]	
	One function calls another SOMEHOW if there is some path from the first to the other. That is, if F1 calls F2, and F2 calls F3, then F1 CALLS F3 SOMEHOW.	
	This information is not stored directly in the database; instead, Masterscope stores only information about direct function calls, and (re)computes the CALL SOMEHOW relation as necessary.	
USE	[Masterscope Relation]	
	If unmodified, the relation USE denotes variable usage in any way; it is the union of the relations SET, SMASH, TEST, and REFERENCE.	
SET	[Masterscope Relation]	
	A function SETs a variable if the function contains a form (SETQ var), (SETQQ var), etc.	
SMASH	[Masterscope Relation]	
	A function SMASHes a variable if the function calls a destructive list operation (RPLACA, RPLACD, DREMOVE, SORT, etc.) on the value of that variable. Masterscope will also find instances where the operation is performed on a "part" of the value of the variable; for example, if a function contains a form (RPLACA (NTH X 3) T) it will be noted as SMASHING X.	
	Note that if the function contains a sequence (SETQ Y X), (RPLACA Y T) then Y is noted as being smashed, but not X.	
TEST	[Masterscope Relation]	
	A variable is TESTed by a function if its value is only distinguished between NIL and non-NIL. For example, the form (COND ((AND X))) tests the value of X.	
REFERENCE	[Masterscope Relation]	
	This relation includes all variable usage except for SET.	
	The verbs USE, SET, SMASH, TEST and REFERENCE may be modified by the words FREELY or LOCALLY. A variable is used FREELY if it is not bound in the function at the place of its use; alternatively, it is used LOCALLY if the use occurs within a PROG or LAMBDA that binds the variable.  Masterscope also distinguishes between CALL DIRECTLY and	
	CALL INDIRECTLY. A function is called DIRECTLY if it occurs as	

CAR-of-form in a normal evaluation context. A function is called INDIRECTLY if its name appears in a context which does not imply its *immediate* evaluation, for example (SETQ Y (LIST (FUNCTION FOO) 3)). The distinction is whether or not the compiled code of the caller would contain a direct call to the callee. Note that an occurrence of (FUNCTION FOO) as the functional argument to one of the built-in mapping functions which compile open is considered to be a direct call.

In addition, CALL FOR EFFECT (where the value of the function is not used) is distinguished from CALL FOR VALUE.

BIND	[Masterscope Relation]		
	The BIND relation between functions and variables includes both		
	variables bound as function arguments and those bound in an		
	internal PROG or LAMBDA expression.		
USE AS A FIELD	[Masterscope Relation]		
	Masterscope notes all uses of record field names within FETCH,		
	REPLACE or CREATE expressions.		
FETCH	[Masterscope Relation]		
	Use of a field within a FETCH expression.		
REPLACE	[Masterscope Relation]		
	Use of a record field name within a REPLACE or CREATE expression.		
USE AS A RECORD	[Masterscope Relation]		
	Masterscope notes all uses of record names within CREATE or		
	TYPE? expressions. Additionally, in (fetch (FOO FIE) of X), FOO is		
	used as a record name.		

## **USE AS A PROPERTY NAME**

CREATE

[Masterscope Relation]

[Masterscope Relation]

Masterscope notes the property names used in GETPROP, PUTPROP, GETLIS, etc. expressions if the name is quoted. E.g. if a function contains a form (GETPROP X (QUOTE INTERP)), then that function USEs INTERP as a property name.

Use of a record name within a CREATE expression.

### **USE AS A CLISP WORD**

[Masterscope Relation]

Masterscope notes all iterative statement operators and user defined CLISP words as being used as a CLISP word.

MASTERSCOPE

### CONTAIN

[Masterscope Relation]

Files contain functions, records, and variables. This relation is not stored in the database but is computed using the file package.

### **DECLARE AS LOCALVAR**

[Masterscope Relation]

### **DECLARE AS SPECVAR**

[Masterscope Relation]

Masterscope notes internal "calls" to DECLARE from within functions.

The following abbreviations are recognized: FREE = FREELY, LOCAL = LOCALLY, PROP = PROPERTY, REF = REFERENCE. Also, the words A, AN and NAME (after AS) are "noise" words and may be omitted.

Note: Masterscope uses "templates" (page 19.18) to decide which relations hold between functions and their arguments. For example, the information that SORT SMASHes its first argument is contained in the template for SORT. Masterscope initially contains templates for most system functions which set variables, test their arguments, or perform destructive operations. The user may change existing templates or insert new ones in Masterscope's tables via the SETTEMPLATE function (page 19.21).

## 19.1.3 Set Specifications

A "set" is a collection of things (functions, variables, etc.). A set is specified by a set phrase, consisting of a determiner (e.g., ANY, WHICH, WHO) followed by a type (e.g., FUNCTIONS, VARIABLES) followed by a specification (e.g., IN MYFNS, @ SUBRP). The determiner, type and specification may be used alone or in combination. For example, ANY FUNCTIONS IN MYFNS, ANY @ SUBRP, VARIABLES IN GLOBALVARS, and WHO are all acceptable set phrases. Set specifications are explained below:

### 'ATOM

[Masterscope Set Specification]

The simplest way to specify a set consisting of a single thing is by the name of that thing. For example, in the command WHO CALLS 'ERROR, the function ERROR is referred to by its name. Although the 'can be left out, to resolve possible ambiguities names should usually be quoted; e.g., WHO CALLS 'CALLS will return the list of functions which call the function CALLS.

## 'LIST [Masterscope Set Specification] Sets consisting of several atoms may be specified by naming the atoms. For example, the command WHO USES '(A B) returns the list of functions that use the variables A or B. IN EXPRESSION [Masterscope Set Specification] The form EXPRESSION is evaluated, and its value is treated as a list of the elements of a set. For example, IN GLOBALVARS specifies the list of variables in the value of the variable **GLOBALVARS** @ PREDICATE

### [Masterscope Set Specification]

A set may also be specified by giving a predicate which the elements of that set must satisfy. PREDICATE is either a function name, a LAMBDA expression, or an expression in terms of the variable X. The specification @ PREDICATE represents all atom for which the value of PREDICATE is non-NIL. For example, @ **EXPRP** specifies all those atoms which have expr definitions; @ (STRPOSL X CLISPCHARRAY) specifies those atoms which contain CLISP characters. The universe to be searched is either determined by the context within the command (e.g., in WHO IN FOOFNS CALLS ANY NOT @ GETD, the predicate is only applied to functions which are called by any functions in the list FOOFNS), or in the extreme case, the universe defaults to the entire set of things which have been noticed by Masterscope, as in the command WHO IS @ EXPRP.

### LIKE ATOM

### [Masterscope Set Specification]

ATOM may contain ESCs; it is used as a pattern to be matched (as in the editor). For example, WHO LIKE /R\$ IS CALLED BY ANY would find both /RPLACA and /RPLNODE.

A set may also be specified by giving a relation its members must have with the members of another set:

### **RELATIONING SET**

### [Masterscope Set Specification]

RELATIONING is used here generically to mean any of the relation words in the present participle form (possibly with a modifier), e.g., USING, SETTING, CALLING, BINDING. RELATIONING SET specifies the set of all objects which have that relation with some element of SET. For example, CALLING X specifies the set of functions which call the function X; USING ANY IN FOOVARS FREELY specifies the set of functions which uses freely any variable in the value of FOOVARS.

RELATIONED BY SET	[Masterscope Set Specification]
RELATIONED IN SET	[Masterscope Set Specification]
	This is similar to the <i>RELATION</i> ING construction. For example, CALLED BY ANY IN FOOFNS represents the set of functions which are called by any element of FOOFNS; USED FREELY BY ANY CALLING ERROR is the set of variables which are used freely by any function which also calls the function ERROR.
BLOCKTYPE OF FUNCTIONS	[Masterscope Set Specification]
BLOCKTYPE ON FILES	[Masterscope Set Specification]
	These phrases allow the user to ask about BLOCKS declarations on files (see page 18.17). <i>BLOCKTYPE</i> is one of LOCALVARS, SPECVARS, GLOBALVARS, ENTRIES, BLKFNS, BLKAPPLYFNS, or RETFNS.
	BLOCKTYPE OF FUNCTIONS specifies the names which are declared to be BLOCKTYPE in any blocks declaration which contain any of FUNCTIONS (a "set" of functions). The "functions" in FUNCTIONS can either be block names or just functions in a block. For example, WHICH ENTRIES OF ANY CALLING'Y BIND ANY GLOBALVARS ON 'FOO.
	BLOCKTYPE ON FILES specifies all names which are declared to be BLOCKTYPE on any of the given FILES (a "set" of files).
FIELDS OF SET	[Masterscope Set Specification]
	SET is a set of records. This denotes the field names of those records. For example, the command WHO USES ANY FIELDS OF BRECORD returns the list of all functions which do a fetch or replace with any of the field names declared in the record declaration of BRECORD.
KNOWN	[Masterscope Set Specification]
	The set of all functions which have been analyzed. For example, the command WHO IS KNOWN will print out the list of functions which have been analyzed.
THOSE	[Masterscope Set Specification]
	The set of things printed out by the last Masterscope question. For example, following the command WHO IS USED FREELY BY PARSE, the user could ask WHO BINDS THOSE to find out where

those variables are bound.

### **ON PATH PATHOPTIONS**

[Masterscope Set Specification]

Refers to the set of functions which would be printed by the command SHOW PATHS PATHOPTIONS. For example, IS FOO BOUND BY ANY ON PATH TO 'PARSE tests if FOO might be bound "above" the function PARSE. SHOW PATHS is explained in detail on page 19.15.

Note: sets may also be specified with "relative clauses" introduced by the word THAT, e.g. THE FUNCTIONS THAT BIND 'X.

### 19.1.4 Set Determiners

Set phrases may be preceded by a determiner. A determiner is one of the words THE, ANY, WHO or WHICH. The "question" determiners (WHO and WHICH) are only meaningful in some of the commands, namely those that take the form of questions. ANY and WHO (or WHOM) can be used alone; they are "wild-card" elements, e.g., the command WHO USES ANY FREELY, will print out the names of all (known) functions which use any variable freely. If the determiner is omitted, ANY is assumed; e.g. the command WHO CALLS '(PRINT PRIN1 PRIN2) will print the list of functions which call any of PRINT, PRIN1, PRIN2. THE is also allowed, e.g. WHO USES THE RECORD FIELD FIELDX.

### 19.1.5 Set Types

Any set phrase has a *type*; that is, a set may specify either functions, variables, files, record names, record field names or property names. The type may be determined by the context within the command (e.g., in CALLED BY ANY ON FOO, the set ANY ON FOO is interpreted as meaning the *functions* on FOO since only functions can be CALLED), or the type may be given explicitly by the user (e.g., FUNCTIONS ON FIE). The following types are recognized: FUNCTIONS, VARIABLES, FILES, PROPERTY NAMES, RECORDS, FIELDS, I.S.OPRS. Also, the abbreviations FNS, VARS, PROPNAMES or the singular forms FUNCTION, FN, VARIABLE, VAR, FILE, PROPNAME, RECORD, FIELD are recognized. Note that most of these types correspond to built-in "file package types" (see page 17.21).

The type is used by Masterscope in a variety of ways when interpreting the set phrase:

(1) Set types are used to disambiguate possible parsings. For example, both commands WHO SETS ANY BOUND IN X OR USED BY Y and WHO SETS ANY BOUND IN X OR CALLED BY Y have the

same general form. However, the first case is parsed as WHO SETS ANY (BOUND BY X OR USED BY Y) since both BOUND BY X and USED BY Y refer to variables; while the second case as WHO SETS ANY BOUND IN (X OR CALLED BY Y), since CALLED BY Y and X must refer to functions. Note that parentheses may be used to group phrases.

- (2) The type is used to determine the modifier for USE: FOO USES WHICH RECORDS is equivalent to FOO USES WHO AS A RECORD FIELD.
- (3) The interpretation of **CONTAIN** depends on the type of its object: the command **WHAT FUNCTIONS** ARE **CONTAINED IN MYFILE** prints the list of functions in **MYFILE**; **WHAT RECORDS ARE ON MYFILE** prints the list of records.
- (4) The implicit "universe" in which a set expression is interpreted depends on the type: ANY VARIABLES @ GETD is interpreted as the set of all variables which have been noticed by Masterscope (i.e., bound or used in any function which has been analyzed) that also have a definition. ANY FUNCTIONS @ (NEQ (GETTOPVAL X) 'NOBIND) is interpreted as the set of all functions which have been noticed (either analyzed or called by a function which has been analyzed) that also have a top-level value.

## 19.1.6 Conjunctions of Sets

Sets may be joined by the conjunctions AND and OR or preceded by NOT to form new sets. AND is always interpreted as meaning "intersection"; OR as "union", while NOT means "complement". For example, the set CALLING X AND NOT CALLED BY Y specifies the set of all functions which call the function X but are not called by Y.

Masterscope's interpretation of AND and OR follow LISP conventions rather than the conventional English interpretation. For example "calling X and Y" would, in English, be interpreted as the intersection of (CALLING X) and (CALLING Y); but Masterscope interprets CALLING X AND Y as CALLING ('X AND 'Y); which is the null set. Only sets may be joined with conjunctions: joining modifiers, as in USING X AS A RECORD FIELD OR PROPERTY NAME, is not allowed; in this case, the user must say USING X AS A RECORD FIELD OR USING X AS A PROPERTY NAME.

As described above, the type of sets is used to disambiguate parsings. The algorithm used is to first try to match the type of the phrases being joined and then try to join with the longest preceding phrase. In any case, the user may group phrases with parentheses to specify the manner in which conjunctions should be parsed.

MASTERSCOPE

19.14

### 19.2 SHOW PATHS

In trying to work with large programs, the user can lose track of the hierarchy of functions. The Masterscope SHOW PATHS command aids the user by providing a map showing the calling structure of a set of functions. SHOW PATHS prints out a tree structure showing which functions call which other functions. For example, the command SHOW PATHS FROM MSPARSE will print out the structure of Masterscope's parser:

### 1.MSPARSE MSINIT MSMARKINVALID MSINITH MSINITH 3. **MSINTERPRET MSRECORDFILE MSPRINTWORDS** 4. 5. PARSECOMMAND GETNEXTWORD CHECKADV PARSERELATION {a} 6. PARSESET {b} 7. PARSEOPTIONS {c} 8. 9. **MERGECONJ GETNEXTWORD (5)** 10. **GETNEXTWORD {5}** 11. **FIXUPTYPES SUBJTYPE** 12. **OBJTYPE** 13. FIXUPCONJUNCTIONS MERGECONJ (9) 14. **MATCHSCORE** 15. **MSPRINTSENTENCE** ------ overflow - a 16.PARSERELATION GETNEXTWORD [5] CHECKADV ----- overflow - b 19.PARSESET PARSESET 20. **GETNEXTWORD {5}** 21. PARSERELATION (6) **SUBPARSE GETNEXTWORD (5)** ----- overflow - c 23.PARSEOPTIONS GETNEXTWORD {5} 24. PARSESET {19}

The above printout displays that the function MSPARSE calls MSINIT, MSINTERPRET, and MSPRINTSENTENCE. MSINTERPRET in turn calls MSRECORDFILE, MSPRINTWORDS. PARSECOMMAND. GETNEXTWORD, FIXUPTYPES. and **FIXUPCONJUNCTIONS.** The numbers in braces {} after a function name are backward references: they indicate that the tree for that function was expanded on a previous line. The lowercase letters in braces are forward references: they indicate that the tree for that function will be expanded below, since there is no more room on the line. The vertical bar is used to keep the output aligned.

MASTERSCOPE

Note: Loading the Browser library package modifies the SHOW PATHS command so the command's output is displayed as an undirected graph.

The SHOW PATHS command takes the form: SHOW PATHS followed by some combination of the following path options:

### FROM SET

## [Masterscope Path Option]

Display the function calls from the elements of SET.

### TO SET

### [Masterscope Path Option]

Display the function calls leading to elements of SET. If TO is given before FROM (or no FROM is given), the tree is "inverted" and a message, (inverted tree) is printed to warn the user that if FN1 appears after FN2 it is because FN1 is called by FN2.

When both FROM and TO are given, the first one indicates a set of functions which are to be displayed while the second restricts the paths that will be traced; i.e., the command SHOW PATHS FROM X TO Y will trace the elements of the set CALLED SOMEHOW BY X AND CALLING Y SOMEHOW.

If TO is not given, TO KNOWN OR NOT @ GETD is assumed; that is, only functions which have been analyzed or which are undefined will be included. Note that Masterscope will analyze a function while printing out the tree if that function has not previously been seen and it currently has an expr definition; thus, any function which can be analyzed will be displayed.

### **AVOIDING SET**

### [Masterscope Path Option]

Do not display any function in SET. AMONG is recognized as a synonym for AVOIDING NOT. For example, SHOW PATHS TO ERROR AVOIDING ON FILE2 will not display (or trace) any function on FILE2.

### **NOTRACE SET**

### [Masterscope Path Option]

Do not trace from any element of SET. NOTRACE differs from AVOIDING in that a function which is marked NOTRACE will be printed, but the tree beyond it will not be expanded; the functions in an AVOIDING set will not be printed at all. For example, SHOW PATHS FROM ANY ON FILE1 NOTRACE ON FILE2 will display the tree of calls eminating from FILE1, but will not expand any function on FILE2.

### **SEPARATE SET**

### [Masterscope Path Option]

Give each element of SET a separate tree. Note that FROM and TO only insure that the designated functions will be displayed. SEPARATE can be used to guarantee that certain functions will

begin new tree structures. **SEPARATE** functions are displayed in the same manner as overflow lines; i.e., when one of the functions indicated by **SEPARATE** is found, it is printed followed by a forward reference (a lower-case letter in braces) and the tree for that function is then expanded below.

### LINELENGTH N

[Masterscope Path Option]

Resets LINELENGTH to N before displaying the tree. The linelength is used to determine when a part of the tree should "overflow" and be expanded lower.

## 19.3 Error Messages

When the user gives Masterscope a command, the command is first parsed, i.e. translated to an internal representation, and then the internal representation is interpreted. If a command cannot be parsed, e.g. if the user typed SHOW WHERE CALLED BY X, the message "Sorry, I can't parse that!" is printed and an error is generated. If the command is of the correct form but cannot be interpreted (e.g., the command EDIT WHERE ANY CONTAINS ANY) Masterscope will print the message "Sorry, that isn't implemented!" and generate an error. If the command requires that some functions having been analyzed (e.g., the command WHO CALLS X) and the database is empty, Masterscope will print the message "Sorry, no functions have been analyzed!" and generate an error.

## 19.4 Macro Expansion

As part of analysis, Masterscope will expand the macro definition of called functions, if they are not otherwise defined (see page 10.21). Masterscope macro expansion is controlled by the variable MSMACROPROPS:

### **MSMACROPROPS**

[Variable]

Value is an ordered list of macro-property names that Masterscope will search to find a macro definition. Only the kinds of macros that appear on MSMACROPROPS will be expanded. All others will be treated as function calls and left unexpanded. Initially (MACRO).

Note: MSMACROPROPS initially contains only MACRO (and not 10MACRO, DMACRO, etc.) in the theory that the

machine-dependent macro definitions are more likely "optimizers".

Note that if you edit a macro, Masterscope will know to reanalyze the functions which call that macro. However, if your macro is of the "computed-macro" style, and it calls functions which you edit, Masterscope will not notice. You must be careful to tell masterscope to REANALYZE the appropriate functions (e.g., if you edit FOOEXPANDER which is used to expand FOO macros, you have to . REANALYZE ANY CALLING FOO.

## 19.5 Affecting Masterscope Analysis

Masterscope analyzes the expr definitions of functions and notes in its database the relations that function has with other functions and with variables. To perform this analysis, Masterscope uses *templates* which describe the behavior of functions. For example, the information that SORT destructively modifies its first argument is contained in the template for SORT. Masterscope initially contains templates for most system functions which set variables, test their arguments, or perform destructive operations.

A template is a list structure containing any of the following atoms:

Ρ	P	Ε
---	---	---

[in Masterscope template]

If an expression appears in this location, there is most likely a parenthesis error.

Masterscope notes this as a "call" to the function "ppe" (lowercase). Therefore, SHOW WHERE ANY CALLS ppe will print out all possible parenthesis errors. When Masterscope finds a possible parenthesis error in the course of analyzing a function definition, rather than printing the usual ".", it prints out a "?" instead.

### NIL

[in Masterscope template]

The expression occuring at this location is not evaluated.

### SET

[in Masterscope template]

A variable appearing at this place is set.

## **SMASH**

[in Masterscope template]

The value of this expression is smashed.

TEST	[in Masterscope template]
	This expression is used as a predicate (that is, the only use of the value of the expression is whether it is <b>NIL</b> or non- <b>NIL</b> ).
PROP	[in Masterscope template]
	The value of this expression is used as a property name. If the expression is of the form (QUOTE ATOM), Masterscope will note that ATOM is USED AS A PROPERTY NAME. For example, the template for GETPROP is (EVAL PROP. PPE).
FUNCTION	[in Masterscope template]
	The expression at this point is used as a functional argument. For example, the template for MAPC is (SMASH FUNCTION FUNCTION . PPE).
FUNCTIONAL	[in Masterscope template]
	The expression at this point is used as a functional argument. This is like <b>FUNCTION</b> , except that Masterscope distinguishes between functional arguments to functions which "compile open" from those that do not. For the latter (e.g. <b>SORT</b> and <b>APPLY</b> ), <b>FUNCTIONAL</b> should be used rather than <b>FUNCTION</b> .
EVAL	[in Masterscope template]
	The expression at this location is evaluated (but not set, smashed, tested, used as a functional argument, etc.).
RETURN	[in Masterscope template]  The value of the function (of which this is the template) is the
	value of this expression.
TESTRETURN	[in Masterscope template]
	A combination of TEST and RETURN: If the value of the function is non-NIL, then it is returned. For instance, a one-element COND clause is this way.
EFFECT	[in Masterscope template]
	The expression at this location is evaluated, but the value is not used.
FETCH	[in Masterscope template] An atom at this location is a field which is fetched.
REPLACE	[in Masterscope template]
	An atom at this location is a field which is replaced.

RECORD	[in Masterscope template]
	An atom at this location is used as a record name.
CDCATE	[in Masterscone template]
CREATE	[in Masterscope template] An atom at this location is a record which is created.
	An atom at this location is a record which is a catego.
BIND	[in Masterscope template]
	An atom at this location is a variable which is bound.
CALL	[in Masterscope template]
	An atom at this location is a function which is called.
CLISP	[in Masterscope template]  An atom at this location is used as a CLISP word.
	All atom at this location is used as a CLISF Word.
!	[in Masterscope template]
	This atom, which can only occur as the first element of a template, allows one to specify a template for the CAR of the function form. If! doesn't appear, the CAR of the form is treated as if it had a CALL specified for it. In other words, the templates ( EVAL) and (! CALL EVAL) are equivalent.
	If the next atom after a ! is NIL, this specifies that the function name should not be remembered. For example, the template for AND is (! NIL TEST RETURN), which means that if you see an "AND", don't remember it as being called. This keeps the Masterscope database from being cluttered by too many uninteresting relations; Masterscope also throws away relations for COND, CAR, CDR, and a couple of others.
	In addition to the above atoms which occur in templates, there are some "special forms" which are lists keyed by their CAR.
TEMPLATE	[in Masterscope template]
	Any part of a template may be preceded by the atom (two periods) which specifies that the template should be repeated an indefinite number $(N > = 0)$ of times to fill out the expression. For example, the template for COND might be ( (TEST EFFECT RETURN)) while the template for SELECTQ is (EVAL (NIL EFFECT RETURN) RETURN).
(BOTH TEMPLATE 1 TEMPLA	ATE <sub>2</sub> ) [in Masterscope template]
- Andrew Control of the Control of t	Analyze the current expression twice, using the each of the

templates in turn.

#### (IF EXPRESSION TEMPLATE 1 TEMPLATE 2)

[in Masterscope template]

Evaluate EXPRESSION at analysis time (the variable EXPR will be bound to the expression which corresponds to the IF), and if the result is non-NIL, use TEMPLATE<sub>1</sub>, otherwise TEMPLATE<sub>2</sub>. If EXPRESSION is a literal atom, it is APPLY'd to EXPR. For example, (IF LISTP (RECORD FETCH) FETCH) specifies that if the current expression is a list, then the first element is a record name and the second element a field name, otherwise it is a field name.

#### (@ EXPRFORM TEMPLATEFORM)

[in Masterscope template]

Evaluate EXPRFORM giving EXPR, evaluate TEMPLATEFORM giving TEMPLATE. Then analyze EXPR with TEMPLATE. @ lets the user compute on the fly both a template and an expression to analyze with it. The forms can use the variable EXPR, which is bound to the current expression.

#### (MACRO . MACRO)

[in Masterscope template]

MACRO is interpreted in the same way as a macro (see page 10.21) and the resulting form is analyzed. If the template is the atom MACRO alone, Masterscope will use the MACRO property of the function itself. This is useful when analyzing code which contains calls to user-defined macros. If the user changes a macro property (e.g. by editing it) of an atom which has template of MACRO, Masterscope will mark any function which used that macro as needing to be reanalyzed.

Some examples of templates:

function:

template:

**DREVERSE** 

(SMASH. PPE)

**AND** 

(! NIL TEST .. RETURN)

**MAPCAR** 

(EVAL FUNCTION FUNCTION)

COND

(! NIL .. (IF CDR (TEST .. EFFECT RETURN) (TESTRETURN . PPE)))

Templates may be changed and new templates defined using the functions:

(GETTEMPLATE FN)

[Function]

Returns the current template of FN.

#### (SETTEMPLATE FN TEMPLATE)

[Function]

Changes the template for the function FN and returns the old value. If any functions in the database are marked as calling FN, they will be marked as needing re-analysis.

### 19.6 Data Base Updating

Masterscope is interfaced to the editor and file package so that it notes whenever a function has been changed, either through editing or loading in a new definition. Whenever a command is given which requires knowing the information about a specific function, if that function has been noted as being changed, the function is automatically re-analyzed before the command is interpreted. If the command requires that all the information in the database be consistent (e.g., the user asks WHO CALLS X) then all functions which have been marked as changed are re-analyzed.

### 19.7 Masterscope Entries

#### (CALLS FN USEDATABASE —)

[Function]

FN can be a function name, a definition, or a form. Note: CALLS will also work on compiled code. CALLS returns a list of four elements: a list of all the functions called by FN, a list of all the variables bound in FN, a list of all the variables used freely in FN, and a list of the variables used globally in FN. For the purpose of CALLS, variables used freely which are on GLOBALVARS or have a property GLOBALVAR value T are considered to be used globally. If USEDATABASE is NIL (or FN is not a litatom), CALLS will perform a one-time analysis of FN. Otherwise (i.e. if USEDATABASE is non-NIL and FN a function name), CALLS will use the information in Masterscope's database (FN will be analyzed first if necessary).

#### (CALLSCCODE FN — —)

[Function]

The sub-function of CALLS which analyzes compiled code. CALLSCCODE returns a list of five elements: a list of all the functions called via "linked" function calls (not implemented in Interlisp-D), a list of all functions called regularly, a list of variables bound in FN, a list of variables used freely, and a list of variables used globally.

#### (FREEVARS FN USEDATABASE)

[Function]

Equivalent to (CADDR (CALL3 FN USEDATABASE)). Returns the list of variables used freely within FN.

#### (MASTERSCOPE COMMAND ---)

[Function]

Top level entry to Masterscope. If COMMAND is NIL, will enter into an executive in which the user may enter commands. If

19.22

**COMMAND** is not **NIL**, the command is interpreted and **MASTERSCOPE** will return the value that would be printed by the command. Note that only the question commands return meaningful values.

#### (SETSYNONYM PHRASE MEANING —)

[Function]

Defines a new synonym for Masterscope's parser. Both OLDPHRASE and NEWPHRASE are words or lists of words; anywhere OLDPHRASE is seen in a command, NEWPHRASE will be substituted. For example, (SETSYNONYM 'GLOBALS '(VARS IN GLOBALVARS OR @(GETPROP X 'GLOBALVAR))) would allow the user to refer with the single word GLOBALS to the set of variables which are either in GLOBALVARS or have a GLOBALVAR property.

The following functions are provided for users who wish to write their own routines using Masterscope's database:

#### (PARSERELATION RELATION)

[Function]

**RELATION** is a relation phrase; e.g., (PARSERELATION '(USE FREELY)). PARSERELATION returns an internal representation for *RELATION*. For use in conjunction with GETRELATION.

### (GETRELATION ITEM RELATION INVERTED)

[Function]

RELATION is an internal representation as returned by PARSERELATION (if not, GETRELATION will first perform (PARSERELATION RELATION)); ITEM is an atom. GETRELATION returns the list of all atoms which have the given relation to ITEM. For example, (GETRELATION 'X '(USE FREELY)) returns the list of variables that X uses freely. If INVERTED is T, the inverse relation is used; e.g. (GETRELATION 'X '(USE FREELY) T) returns the list of functions which use X freely.

If *ITEM* is **NIL**, **GETRELATION** will return the list of atoms which have *RELATION* with *any* other item; i.e., answers the question **WHO** *RELATIONS* **ANY**. Note that **GETRELATION** does *not* check to see if *ITEM* has been analyzed, or that other functions that have been changed have been re-analyzed.

#### (TESTRELATION ITEM RELATION ITEM2 INVERTED)

[Function]

Equivalent to (MEMB ITEM2 (GETRELATION ITEM RELATION INVERTED)), that is, tests if ITEM and ITEM2 are related via RELATION. If ITEM2 is NIL, the call is equivalent to (NOT (NULL (GETRELATION ITEM RELATION INVERTED))), i.e., TESTRELATION tests if ITEM has the given RELATION with any other item.

#### (MAPRELATION RELATION MAPFN)

[Function]

Calls the function *MAPFN* on every pair of items related via *RELATION*. If (NARGS *MAPFN*) is 1, then *MAPFN* is called on every item which has the given *RELATION* to *any* other item.

#### (MSNEEDUNSAVE FNS MSG MARKCHANGEFLG)

[Function]

Used to mark functions which depend on a changed record declaration (or macro, etc.), and which must be LOADed or UNSAVEd (see below). FNS is a list of functions to be marked, and MSG is a string describing the records, macros, etc. on which they depend. If MARKCHANGEFLG is non-NIL, each function in the list is marked as needing re-analysis.

#### (UPDATEFN FN EVENIFVALID —)

[Function]

Equivalent to the command ANALYZE 'FN; that is, UPDATEFN will analyze FN if FN has not been analyzed before or if it has been changed since the time it was analyzed. If EVENIFVALID is non-NIL, UPDATEFN will re-analyze FN even if Masterscope thinks it has a valid analysis in the database.

#### (UPDATECHANGED)

[Function]

Performs (UPDATEFN FN) on every function which has been marked as changed.

#### (MSMARKCHANGED NAME TYPE REASON)

[Function]

Mark that *NAME* has been changed and needs to be reanalyzed. See MARKASCHANGED, page 17.17.

#### (DUMPDATABASE FNLST)

[Function]

Dumps the current Masterscope database on the current output file in a LOADable form. If FNLST is not NIL, DUMPDATABASE will only dump the information for the list of functions in FNLST. The variable DATABASECOMS is initialized to ((E (DUMPDATABASE))); thus, the user may merely perform (MAKEFILE 'DATABASE.EXTENSION) to save the current Masterscope database. If a Masterscope database already exists when a DATABASE file is loaded, the database on the file will be merged with the one in core. Note that functions whose definitions are different from their definition when the database was made must be REANALYZEd if their new definitions are to be noticed.

The Databasefns library package provides a more convenient way of saving data bases along with the source files which they correspond to.

### 19.8 Noticing Changes that Require Recompiling

When a record declaration, iterative statement operator or macro is changed, and Masterscope has "noticed" a use of that declaration or macro (i.e. it is used by some function known about in the data base), Masterscope will alert the user about those functions which might need to be re-compiled (e.g. they do not currently have expr definitions). Extra functions may be noticed; for example if FOO contains (fetch (REC X) --), and some declaration other than REC which contains X is changed, Masterscope will still think that FOO needs to be loaded/unsaved. The functions which need recompiling are added to the list MSNEEDUNSAVE and a message is printed out:

The functions FN1, FN2,... use macros which have changed. Call UNSAVEFNS() to load and/or unsave them.

In this situation, the following function is useful:

#### (UNSAVEFNS —)

[Function]

Uses LOADFNS or UNSAVEDEF to make sure that all functions in the list MSNEEDUNSAVE have expr definitions, and then sets MSNEEDUNSAVE to NIL.

Note: If RECOMPILEDEFAULT (page 18.16) is set to CHANGES, UNSAVEFNS prints out "WARNING: you must set RECOMPILEDEFAULT to EXPRS in order to have these functions recompiled automatically".

## 19.9 Implementation Notes

Masterscope keeps a database of the relations noticed when functions are analyzed. The relations are intersected to form "primitive relationships" such that there is little or no overlap of any of the primitives. For example, the relation SET is stored as the union of SET LOCAL and SET FREE. The BIND relation is divided into BIND AS ARG, BIND AND NOT USE, and SET LOCAL, SMASH LOCAL, etc. Splitting the relations in this manner reduces the size of the database considerably, to the point where it is reasonable to maintain a Masterscope database for a large system of functions during a normal debugging session.

Each primitive relationship is stored in a pair of hash-tables, one for the "forward" direction and one for the "reverse". For example, there are two hash tables, USE AS PROPERTY and USED AS PROPERTY. To retrieve the information from the database, Masterscope performs unions of the hash-values. For example, to answer FOO BINDS WHO Masterscope will look in all of the tables which make up the BIND relation. The "internal

representation" returned by **PARSERELATION** is just a list of dotted pairs of hash-tables. To perform **GETRELATION** requires only mapping down that list, doing **GETHASH**'s on the appropriate hash-tables and **UNION**ing the result.

Hash tables are used for a variety of reasons: storage space is smaller; it is not necessary to maintain separate lists of which functions have been analyzed (a special table, DOESN'T DO ANYTHING is maintained for functions which neither call other functions nor bind or use any variables); and accessing is relatively fast. Within any of the tables, if the hash-value would be a list of one atom, then the atom itself, rather than the list, is stored as the hash-value. This also reduces the size of the database significantly.

TOC.2 TABLE OF CONTENTS

A surprisingly large percentage of the errors made by Interlisp users are of the type that could be corrected by another Lisp programmer without any information about the purpose of the program or expression in question, e.g., misspellings, certain kinds of parentheses errors, etc. To correct these types of errors we have implemented in Interlisp a DWIM facility, short for Do-What-I-Mean. DWIM is called automatically whenever an error occurs in the evaluation of an Interlisp expression. (Currently, DWIM only operates on unbound atoms and undefined function errors.) DWIM then proceeds to try to correct the mistake using the current context of computation plus information about what the user had previously been doing, (and what mistakes he had been making) as guides to the remedy of the error. If DWIM is able to make the correction, the computation continues as though no error had occurred. Otherwise, the procedure is the same as though DWIM had not intervened: a break occurs, or an unwind to the last ERRORSET (page 14.21). The following protocol illustrates the operation of DWIM.

For example, suppose the user defines the factorial function (FACT N) as follows:

```
←DEFINEQ((FACT (LAMBDA (N) (COND ((ZEROP NO 1) ((T (ITIMS N (FACCT 9SUB1 N) (FACT)
```

←

Note that the definition of FACT contains several mistakes: ITIMES and FACT have been misspelled; the 0 in N0 was intended to be a right parenthesis, but the shift key was not depressed; similarly, the 9 in 9SUB1 was intended to be a left parenthesis; and finally, there is an extra left parenthesis in front of the T that begins the final clause in the conditional.

```
= PRETTYPRINT
= FACT

(FACT
[LAMBDA (N)
(COND
((ZEROP NO 1)
((T (ITIMS N (FACCT 9SUB1 N]))
```

←PRETTYPRNT((FACCT)

<del>--</del>

After defining FACT, the user wishes to look at its definition using PRETTYPRINT, which he unfortunately misspells. Since there is no function PRETTYPRNT in the system, an undefined function error occurs, and DWIM is called. DWIM invokes its spelling corrector, which searches a list of functions frequently used (by this user) for the best possible match. Finding one that is extremely close, DWIM proceeds on the assumption that PRETTYPRNT meant PRETTYPRINT, notifies the user of this, and calls PRETTYPRINT.

At this point, **PRETTYPRINT** would normally print (**FACCT NOT PRINTABLE**) and exit, since **FACCT** has no definition. Note that this is *not* an Interlisp error condition, so that DWIM would not be called as described above. However, it is obviously not what the user *meant*.

This sort of mistake is corrected by having PRETTYPRINT itself explicitly invoke the spelling corrector portion of DWIM whenever given a function with no EXPR definition. Thus, with the aid of DWIM PRETTYPRINT is able to determine that the user wants to see the definition of the function FACT, and proceeds accordingly.

The user now calls FACT. During its execution, five errors occur, and DWIM is called five times. At each point, the error is corrected, a message is printed describing the action taken, and the computation is allowed to continue as if no error had occurred. Following the last correction, 6 is printed, the value of (FACT 3). Finally, the user prettyprints the new, now correct, definition of FACT.

In this particular example, the user was shown operating in TRUSTING mode, which gives DWIM carte blanche for most

corrections. The user can also operate in CAUTIOUS mode, in which case DWIM will inform him of intended corrections before they are made, and allow the user to approve or disapprove of them. If DWIM was operating in CAUTIOUS mode in the example above, it would proceed as follows:

For most corrections, if the user does not respond in a specified interval of time, DWIM automatically proceeds with the correction, so that the user need intervene only when he does not approve. Note that the user responded to the first, second, and fifth questions; DWIM responded for him on the third and fourth.

Note: DWIM uses ASKUSER for its interactions with the user (page 26.12). Whenever an interaction is about to take place and the user has typed ahead, ASKUSER types several bells to warn the user to stop typing, then clears and saves the input buffers, restoring them after the interaction is complete. Thus if the user has typed ahead before a DWIM interaction, DWIM will not confuse his type ahead with the answer to its question, nor will his typeahead be lost. The bells are printed by the function PRINTBELLS, which can be advised or redefined for specialized applications, e.g. to flash the screen for a display terminal.

A great deal of effort has gone into making DWIM "smart", and experience with a large number of users indicates that DWIM works very well; DWIM seldom fails to correct an error the user feels it should have, and almost never mistakenly corrects an error. However, it is important to note that even when DWIM is wrong, no harm is done: since an error had occurred, the user would have had to intervene anyway if DWIM took no action. Thus, if DWIM mistakenly corrects an error, the user simply interrupts or aborts the computation, UNDOes the DWIM change using UNDO (page 13.13), and makes the correction he would have had to make without DWIM. An exception is if DWIM's correction mistakenly caused a destructive computation to be initiated, and information was lost before the user could interrupt. We have not yet had such an incident occur.

DWIM

(DWIM X) [Function]

Used to enable/disable DWIM. If X is the litatom C, DWIM is enabled in CAUTIOUS mode, so that DWIM will ask the user before making corrections. If X is T, DWIM is enabled in TRUSTING mode, so DWIM will make most corrections automatically. If X is NIL, DWIM is disabled. Interlisp initially has DWIM enabled in CAUTIOUS mode.

**DWIM** returns **CAUTIOUS**, **TRUSTING** or **NIL**, depending to what mode it has just been put into.

For corrections to expressions typed in by the user for immediate execution (typed into LISPX, page 13.35), DWIM always acts as though it were in TRUSTING mode, i.e., no approval necessary. For certain types of corrections, e.g., run-on spelling corrections, 9-0 errors, etc., DWIM always acts like it was in CAUTIOUS mode, and asks for approval. In either case, DWIM always informs the user of its action as described below.

## 20.1 Spelling Correction Protocol

One type of error that DWIM can correct is the misspelling of a function or a variable name. When an unbound litatom or undefined function error occurs, DWIM tries to correct the spelling of the bad litatom. If a litatom is found whose spelling is "close" to the offender, DWIM proceeds as follows:

If the correction occurs in the typed-in expression, DWIM prints = CORRECT-SPELLING<sup>CT</sup> and continues evaluating the expression. For example:

```
←(SETQ FOO (IPLUSS 1 2))
```

= IPLUS

3

If the correction does not occur in type-in, DWIM prints

BAD-SPELLING [IN FUNCTION-NAME] -> CORRECT-SPELLING

The appearance of -> is to call attention to the fact that the user's function will be or has been changed.

Then, if DWIM is in **TRUSTING** mode, it prints a carriage return, makes the correction, and continues the computation. If DWIM is in **CAUTIOUS** mode, it prints a few spaces and ? and then wait for approval. The user then has six options:

- (1) Type Y. DWIM types es, and proceeds with the correction.
- (2) Type N. DWIM types o, and does not make the correction.

- (3) Type †. DWIM does not make the correction, and furthermore guarantees that the error will not cause a break.
- (4) Type control-E. For error correction, this has the same effect as typing **N**.
- (5) Do nothing. In this case DWIM waits for **DWIMWAIT** seconds, and if the user has not responded, DWIM will type ... followed by the default answer.

The default on spelling corrections is determined by the value of the variable FIXSPELLDEFAULT, whose top level value is initially Y.

(6) Type space or carriage-return. In this case DWIM will wait indefinitely. This option is intended for those cases where the user wants to think about his answer, and wants to insure that DWIM does not get "impatient" and answer for him.

The procedure for spelling correction on other than Interlisp errors is analogous. If the correction is being handled as type-in, DWIM prints = followed by the correct spelling, and returns it to the function that called DWIM. Otherwise, DWIM prints the incorrect spelling, followed by the correct spelling. Then, if DWIM if in TRUSTING mode, DWIM prints a carriage-return and returns the correct spelling. Otherwise, DWIM prints a few spaces and a ? and waits for approval. The user can then respond with Y, N, control-E, space, carriage return, or do nothing as described above.

Note that the spelling corrector itself is not ERRORSET protected like the DWIM error correction routines. Therefore, typing N and typing control-E may have different effects when the spelling corrector is called directly. The former simply instructs the spelling corrector to return NIL, and lets the calling function decide what to do next; the latter causes an error which unwinds to the last ERRORSET, however far back that may be.

### 20.2 Parentheses Errors Protocol

When an unbound litatom or undefined error occurs, and the offending litatom contains 9 or 0, DWIM tries to correct errors caused by typing 9 for left parenthesis and 0 for right parenthesis. In these cases, the interaction with the user is similar to that for spelling correction. If the error occurs in type-in, DWIM types = CORRECTION<sup>CT</sup>, and continues evaluating the expression. For example:

←(SETQ FOO 9IPLUS 1 2]

= (IPLUS

3

If the correction does not occur in type-in, DWIM prints

BAD-ATOM [IN FUNCTION-NAME] -> CORRECTION ?

and then waits for approval. The user then has the same six options as for spelling correction, except the waiting time is 3\*DWIMWAIT seconds. If the user types Y, DWIM then operates as if it were in TRUSTING mode, i.e., it makes the correction and prints its message.

Note: Actually, DWIM uses the value of the variables LPARKEY and RPARKEY to determine the corresponding lower case character for left and right parentheses. LPARKEY and RPARKEY are initially 9 and 0 respectively, but they can be reset for other keyboard layouts, e.g., on some terminals left parenthesis is over 8, and right parenthesis is over 9.

## 20.3 Undefined Function T Errors

When an undefined function error occurs, and the offending function is T, DWIM tries to correct certain types of parentheses errors involving a T clause in a conditional. DWIM recognizes errors of the following forms:

(COND --) (T --) The T clause appears outside and immediately following the COND.

(COND -- (-- & (T --))) The T clause appears inside a previous clause.

(COND -- ((T --))) The T clause has an extra pair of parentheses around it.

For undefined function errors that are not one of these three types, DWIM takes no corrective action at all, and the error will occur.

If the error occurs in type-in, DWIM simply types T FIXED and makes the correction. Otherwise if DWIM is in TRUSTING mode, DWIM makes the correction and prints the message:

[IN FUNCTION-NAME] {BAD-COND} -> {CORRECTED-COND}

If DWIM is in CAUTIOUS mode, DWIM prints

UNDEFINED FUNCTION T
[IN FUNCTION-NAME] FIX?

and waits for approval. The user then has the same options as for spelling corrections and parenthesis errors. If the user types Y or defaults, DWIM makes the correction and prints its message.

Having made the correction, DWIM must then decide how to proceed with the computation. In the first case, (COND --) (T --), DWIM cannot know whether the T clause would have been executed if it had been inside of the COND. Therefore DWIM

asks the user CONTINUE WITH T CLAUSE (with a default of YES). If the user types N, DWIM continues with the form after the COND, i.e., the form that originally followed the T clause.

In the second case, (COND -- (-- & (T --))), DWIM has a different problem. After moving the T clause to its proper place, DWIM must return as the value of & as the value of the COND. Since this value is no longer around, DWIM asks the user, OK TO REEVALUATE and then prints the expression corresponding to &. If the user types Y, or defaults, DWIM continues by reevaluating &, otherwise DWIM aborts, and a U.D.F. T error will then occur (even though the COND has in fact been fixed). If DWIM can determine for itself that the form can safely be reevaluated, it does not consult the user before reevaluating. DWIM can do this if the form is atomic, or CAR of the form is a member of the list OKREEVALST, and each of the arguments can safely be reevaluated. For example, (SETQ X (CONS (IPLUS Y Z) W)) is safe to reevaluate because SETQ, CONS, and IPLUS are all on OKREEVALST.

In the third case, (COND -- ((T --))), there is no problem with continuation, so no further interaction is necessary.

## 20.4 DWIM Operation

Whenever the interpreter encounters an atomic form with no binding, or a non-atomic form CAR of which is not a function or function object, it calls the function FAULTEVAL. Similarly, when APPLY is given an undefined function, FAULTAPPLY is called. When DWIM is enabled, FAULTEVAL and FAULTAPPLY are redefined to first call the DWIM package, which tries to correct the error. If DWIM cannot decide how to fix the error, or the user disapproves of DWIM's correction (by typing N), or the user types control-E, then FAULTEVAL and FAULTAPPLY cause an error or break. If the user types ↑ to DWIM, DWIM exits by performing (RETEVAL 'FAULTEVAL '(ERROR!)), so that an error will be generated at the position of the call to FAULTEVAL.

If DWIM can (and is allowed to) correct the error, it exits by performing RETEVAL of the corrected form, as of the position of the call to FAULTEVAL or FAULTAPPLY. Thus in the example at the beginning of the chapter, when DWIM determined that ITIMS was ITIMES misspelled, DWIM called RETEVAL with (ITIMES N (FACCT 9SUB1 N)). Since the interpreter uses the value returned by FAULTEVAL exactly as though it were the value of the erroneous form, the computation will thus proceed exactly as though no error had occurred.

In addition to continuing the computation, DWIM also repairs the cause of the error whenever possible; in the above example, DWIM also changed (with RPLACA) the expression (ITIMS N (FACCT 9SUB1 N)) that caused the error. Note that if the user's program had computed the form and called EVAL, it would not be possible to repair the cause of the error, although DWIM could correct the misspelling each time it occurred.

Error correction in DWIM is divided into three categories: unbound atoms, undefined CAR of form, and undefined function in APPLY. Assuming that the user approves DWIM's corrections, the action taken by DWIM for the various types of errors in each of these categories is summarized below.

#### 20.4.1 DWIM Correction: Unbound Atoms

If DWIM is called as the result of an unbound atom error, it proceeds as follows:

(1) If the first character of the unbound atom is ', DWIM assumes that the user (intentionally) typed 'ATOM for (QUOTE ATOM) and makes the appropriate change. No message is typed, and no approval is requested.

If the unbound atom is just 'itself, DWIM assumes the user wants the *next* expression quoted, e.g., (CONS X '(A B C)) will be changed to (CONS X (QUOTE (A B C))). Again no message will be printed or approval asked. If no expression follows the ', DWIM gives up.

Note: ' is normally defined as a read-macro character which converts 'FOO to (QUOTE FOO) on input, so DWIM will not see the ' in the case of expressions that are typed-in.

- (2) If CLISP (page 21.1) is enabled, and the atom is part of a CLISP construct, the CLISP transformation is performed and the result returned. For example, N-1 is transformed to (SUB1 N), and (... FOO←3 ...) is transformed into (... (SETQ FOO 3) ...).
- (3) If the atom contains an 9 (actually LPARKEY, see page 20.14), DWIM assumes the 9 was intended to be a left parenthesis, and calls the editor to make appropriate repairs on the expression containing the atom. DWIM assumes that the user did not notice the mistake, i.e., that the entire expression was affected by the missing left parenthesis. For example, if the user types (SETQ X (LIST (CONS 9CAR Y) (CDR Z)) Y), the expression will be changed to (SETQ X (LIST (CONS (CAR Y) (CDR Z)) Y)). Note that the 9 does not have to be the first character of the atom: DWIM will handle (CONS X9CAR Y) correctly.
- (4) If the atom contains a 0 (actually RPARKEY, see page 20.14), DWIM assumes the 0 was intended to be a right parenthesis and operates as in the case above.

- (5) If the atom begins with a 7, the 7 is treated as a '. For example, 7F00 becomes 'F00, and then (QUOTE F00).
- (6) The expressions on DWIMUSERFORMS (see page 20.11) are evaluated in the order that they appear. If any of these expressions returns a non-NIL value, this value is treated as the form to be used to continue the computation, it is evaluated and its value is returned by DWIM.
- (7) If the unbound atom occurs in a function, DWIM attempts spelling correction using the LAMBDA and PROG variables of the function as the spelling list.
- (8) If the unbound atom occurred in a type-in to a break, DWIM attempts spelling correction using the LAMBDA and PROG variables of the broken function as the spelling list.
- (9) Otherwise, DWIM attempts spelling correction using SPELLINGS3 (see page 20.17).
- (10) If all of the above fail, DWIM gives up.

#### 20.4.2 Undefined CAR of Form

- If DWIM is called as the result of an undefined CAR of form error, it proceeds as follows:
- (1) If CAR of the form is T, DWIM assumes a misplaced T clause and operates as described on page 20.6.
- (2) If CAR of the form is F/L, DWIM changes the "F/L" to "FUNCTION(LAMBDA". For example, (F/L (Y) (PRINT (CAR Y))) is changed to (FUNCTION (LAMBDA (Y) (PRINT (CAR Y))). No message is printed and no approval requested. If the user omits the variable list, DWIM supplies (X), e.g., (F/L (PRINT (CAR X))) is changed to (FUNCTION (LAMBDA (X) (PRINT (CAR X)))). DWIM determines that the user has supplied the variable list when more than one expression follows F/L, CAR of the first expression is not the name of a function, and every element in the first expression is atomic. For example, DWIM will supply (X) when correcting (F/L (PRINT (CDR X)) (PRINT (CAR X))).
- (3) If CAR of the form is a CLISP word (IF, FOR, DO, FETCH, etc.), the indicated CLISP transformation is performed, and the result is returned as the corrected form. See page 21.1.
- (4) If CAR of the form has a function definition, DWIM attempts spelling correction on CAR of the definition using as spelling list the value of LAMBDASPLST, initially (LAMBDA NLAMBDA).
- (5) If CAR of the form has an EXPR or CODE property, DWIM prints CAR-OF-FORM UNSAVED, performs an UNSAVEDEF, and continues. No approval is requested.

- (6) If CAR of the form has a FILEDEF property, the definition is loaded from a file (except when DWIMIFYing). If the value of the property is atomic, the entire file is to be loaded. If the value is a list, CAR is the name of the file and CDR the relevant functions, and LOADFNS will be used. For both cases, LDFLG will be SYSLOAD (see page 17.5). DWIM uses FINDFILE (page 24.32), so that the file can be on any of the directories on DIRECTORIES, initially (NIL NEWLISP LISP LISPUSERS). If the file is found, DWIM types SHALL I LOAD followed by the file name or list of functions. If the user approves, DWIM loads the function(s) or file, and continues the computation.
- (7) If CLISP is enabled, and CAR of the form is part of a CLISP construct, the indicated transformation is performed, e.g., (N←N-1) becomes (SETQ N (SUB1 N)).
- (8) If CAR of the form contains an 9, DWIM assumes a left parenthesis was intended e.g., (CONS9CAR X).
- (9) If CAR of the form contains a 0, DWIM assumes a right parenthesis was intended.
- (10) If CAR of the form is a list, DWIM attempts spelling correction on CAAR of the form using LAMBDASPLST as spelling list. If successful, DWIM returns the corrected expression itself.
- (11) The expressions on **DWIMUSERFORMS** are evaluated in the order they appear. If any returns a non-**NIL** value, this value is treated as the corrected form, it is evaluated, and **DWIM** returns its value.
- (12) Otherwise, DWIM attempts spelling correction using SPELLINGS2 as the spelling list (see page 20.17). When DWIMIFYing, DWIM also attemps spelling correction on function names not defined but previously encountered, using NOFIXFNSLST as a spelling list (see page 21.21).
- (13) If all of the above fail, DWIM gives up.

#### 20.4.3 Undefined Function in APPLY

- If DWIM is called as the result of an undefined function in APPLY error, it proceeds as follows:
- (1) If the function has a definition, DWIM attempts spelling correction on CAR of the definition using LAMBDASPLST as spelling list.
- (2) If the function has an EXPR or CODE property, DWIM prints FN UNSAVED, performs an UNSAVEDEF and continues. No approval is requested.
- (3) If the function has a property FILEDEF, DWIM proceeds as in case 6 of undefined CAR of form.

- (4) If the error resulted from type-in, and CLISP is enabled, and the function name contains a CLISP operator, DWIM performs the indicated transformation, e.g., the user types FOO←(APPEND FIE FUM).
- (5) If the function name contains an **9**, DWIM assumes a left parenthesis was intended, e.g., **EDIT9FOO**].
- (6) If the "function" is a list, DWIM attempts spelling correction on CAR of the list using LAMBDASPLST as spelling list.
- (7) The expressions on DWIMUSERFORMS are evaluated in the order they appear, and if any returns a non-NIL value, this value is treated as the function used to continue the computation, i.e., it will be applied to its arguments.
- (8) DWIM attempts spelling correction using SPELLINGS1 as the spelling list.
- (9) DWIM attempts spelling correction using SPELLINGS2 as the spelling list.
- (10) If all fail, DWIM gives up.

#### 20.5 DWIMUSERFORMS

The variable DWIMUSERFORMS provides a convenient way of adding to the transformations that DWIM performs. example, the user might want to change atoms of the form \$X to (QA4LOOKUP X). Before attempting spelling correction, but after performing other transformations (F/L, 9, 0, CLISP, etc.), DWIM evaluates the expressions on DWIMUSERFORMS in the order they appear. If any expression returns a non-NIL value, this value is treated as the transformed form to be used. If DWIM was called from FAULTEVAL, this form is evaluated and the resulting value is returned as the value of FAULTEVAL. If DWIM is called from FAULTAPPLY, this form is treated as a function to be applied to FAULTARGS, and the resulting value is returned as the value of FAULTAPPLY. If all of the expressions on DWIMUSERFORMS return NIL, DWIM proceeds as though **DWIMUSERFORMS = NIL**, and attempts spelling correction. Note that DWIM simply takes the value and returns it; the expressions on DWIMUSERFORMS are responsible for making any modifications to the original expression. The expressions on **DWIMUSERFORMS** should make the transformation permanent, either by associating it with FAULTX via CLISPTRAN, or by destructively changing FAULTX.

In order for an expression on **DWIMUSERFORMS** to be able to be effective, it needs to know various things about the context of the error. Therefore, several of DWIM's internal variables have

DWIM

	been made SPECVARS (see page 18.5) and are therefore "visible" to DWIMUSERFORMS. Below are a list of those variables that
	may be useful.
FAULTX	[Variable]
	For unbound atom and undefined car of form errors, FAULTX is the atom or form. For undefined function in APPLY errors, FAULTX is the name of the function.
FAULTARGS	[Variable]
	For undefined function in APPLY errors, FAULTARGS is the list of arguments. FAULTARGS may be modified or reset by expressions on DWIMUSERFORMS.
FAULTAPPLYFLG	[Variable]
	Value is T for undefined function in APPLY errors; NIL otherwise. The value of FAULTAPPLYFLG after an expression on DWIMUSERFORMS returns a non-NIL value determines how the latter value is to be treated. Following an undefined function in APPLY error, if an expression on DWIMUSERFORMS sets FAULTAPPLYFLG to NIL, the value returned is treated as a form to be evaluated, rather than a function to be applied.
	FAULTAPPLYFLG is necessary to distinguish between unbound atom and undefined function in APPLY errors, since FAULTARGS may be NIL and FAULTX atomic in both cases.
TAIL	[Variable]
	For unbound atom errors, TAIL is the tail of the expression CAR of which is the unbound atom. <b>DWIMUSERFORMS</b> expression can replace the atom by another expression by performing (/RPLACA TAIL EXPR)
PARENT	[Variable]
	For unbound atom errors, PARENT is the form in which the unbound atom appears. TAIL is a tail of PARENT.
TYPE-IN?	[Variable]
	True if the error occurred in type-in.
FAULTFN	[Variable]
	Name of the function in which error occurred. FAULTFN is TYPE-IN when the error occurred in type-in, and EVAL or APPLY when the error occurred under an explicit call to EVAL or APPLY.

20.12

DWIMIFYFLG	[Variable]	
	True if the error was encountered while <b>DWIMIFY</b> ing (as opposed to happening while running a program).	
EXPR	[Variable]	
	Definition of FAULTFN, or argument to EVAL, i.e., the superform in which the error occurs.	
	The initial value of DWIMUSERFORMS is ((DWIMLOADFNS?)). DWIMLOADFNS? is a function for automatically loading functions from files. If DWIMLOADFNSFLG is T (its initial value), and CAR of the form is the name of a function, and the function is contained on a file that has been noticed by the file package, the function is loaded, and the computation continues.	

# 20.6 DWIM Functions and Variables

DWIMWAIT	[Variable]
	Value is the number of seconds that DWIM will wait before it assumes that the user is not going to respond to a question and uses the default response FIXSPELLDEFAULT.
	DWIM operates by dismissing for 250 milliseconds, then checking to see if anything has been typed. If not, it dismisses again, etc. until DWIMWAIT seconds have elapsed. Thus, there will be a delay of at most 1/4 second before DWIM responds to the user's answer.
FIXSPELLDEFAULT	[Variable]
	If approval is requested for a spelling correction, and user does not respond, defaults to value of FIXSPELLDEFAULT, initially Y. FIXSPELLDEFAULT is rebound to N when DWIMIFYing.
ADDSPELLFLG	[Variable]
	If NIL, suppresses calls to ADDSPELL. Initially T.
NOSPELLFLG	[Variable]
	If T, suppresses all spelling correction. If some other non-NIL value, suppresses spelling correction in programs but not type-in.  NOSPELLFLG is initially NIL. It is rebound to T when compiling from a file.

DWIM

RUNONFLG	[Variable]	
	If NIL, suppresses run-on spelling corrections. Initially NIL.	
DWIMLOADFNSFLG	[Variable]	
	If T, tells DWIM that when it encounters a call to an undefined	
	function contained on a file that has been noticed by the file	
	package, to simply load the function. DWIMLOADFNSFLG is	
	initially <b>T</b> . See page 20.13.	
LPARKEY	[Variable]	
RPARKEY	[Variable]	
RPARKET	DWIM uses the value of the variables LPARKEY and RPARKEY	
	(initially 9 and 0 respectively) to determine the corresponding	
	lower case character for left and right parentheses. LPARKEY	
	and RPARKEY can be reset for other keyboard layouts. For	
	example, on some terminals left parenthesis is over 8, and right	
	parenthesis is over 9.	
OKREEVALST	[Variable]	
	The value of OKREEVALST is a list of functions that DWIM can	
	safely reevaluate. If a form is atomic, or CAR of the form is a	
·	member of OKREEVALST, and each of the arguments can safely	
	be reevaluated, then the form can be safely reevaluated. For	
	example, (SETQ X (CONS (IPLUS Y Z) W)) is safe to reevaluate	
	because SETQ, CONS, and IPLUS are all on OKREEVALST.	
DWIMFLG	[Variable]	
	DWIMFLG = NIL, all DWIM operations are disabled. (DWIM 'C)	
	and (DWIM T) set DWIMFLG to T; (DWIM NIL) sets DWIMFLG to NIL.	
A 222 CV (TT) C		
APPROVEFLG	[Variable]	
	<b>APPROVEFLG = T</b> if DWIM should ask the user for approval before making a correction that will modify the definition of one	
	of his functions; <b>NIL</b> otherwise.	
	When DWIM is put into CAUTIOUS mode with (DWIM 'C) APPROVEFLG is set to T; for TRUSTING mode, APPROVEFLG is set to NIL.	
LAMBDASPLST	[Variable	
FUMBOW3LF3 (	DWIM uses the value of LAMBDASPLST as the spelling list when	
	correcting "bad" function definitions. Initially (LAMBDA NLAMBDA). The user may wish to add to LAMBDASPLST if he elects to define new "function types" via an appropriate	

20.14

**DWIMUSERFORMS** entry. For example, the **QLAMBDAs** of SRI's QLISP are handled in this way.

## 20.7 Spelling Correction

The spelling corrector is given as arguments a misspelled word (word means literal atom), a spelling list (a list of words), and a number: XWORD, SPLST, and REL respectively. Its task is to find that word on SPLST which is closest to XWORD, in the sense described below. This word is called a respelling of XWORD. REL specifies the minimum "closeness" between XWORD and a respelling. If the spelling corrector cannot find a word on SPLST closer to XWORD than REL, or if it finds two or more words equally close, its value is NIL, otherwise its value is the respelling. The spelling corrector can also be given an optional functional argument, FN, to be used for selecting out a subset of SPLST, i.e., only those members of SPLST that satisfy FN will be considered as possible respellings.

The exact algorithm for computing the spelling metric is described later, but briefly "closeness" is inversely proportional to the number of disagreements between the two words, and directly proportional to the length of the longer word. For example, PRTTYPRNT is "closer" to PRETTYPRINT than CS is to CONS even though both pairs of words have the same number of disagreements. The spelling corrector operates by proceeding down SPLST, and computing the closeness between each word and XWORD, and keeping a list of those that are closest. Certain differences between words are not counted as disagreements, for example a single transposition, e.g., CONS to CNOS, or a doubled letter, e.g., CONS to CONSS, etc. In the event that the spelling corrector finds a word on SPLST with no disagreements, it will stop searching and return this word as the respelling. Otherwise, the spelling corrector continues through the entire spelling list. Then if it has found one and only one "closest" word, it returns this word as the respelling. For example, if XWORD is VONS, the spelling corrector will probably return **CONS** as the respelling. However, if XWORD is CONZ, the spelling corrector will not be able to return a respelling, since CONZ is equally close to both CONS and COND. If the spelling corrector finds an acceptable respelling, it interacts with the user as described earlier.

In the special case that the misspelled word contains one or more \$s (escape), the spelling corrector searches for those words on SPLST that match XWORD, where a \$ can match any number of characters (including 0), e.g., FOO\$ matches FOO1 and FOO, but not NEWFOO. \$FOO\$ matches all three. Both completion and

correction may be involved, e.g. RPETTY\$ will match PRETTYPRINT, with one mistake. The entire spelling list is always searched, and if more than one respelling is found, the spelling corrector prints AMBIGUOUS, and returns NIL. For example, CON\$ would be ambiguous if both CONS and COND were on the spelling list. If the spelling corrector finds one and only one respelling, it interacts with the user as described earlier.

For both spelling correction and spelling completion, regardless of whether or not the user approves of the spelling corrector's choice, the respelling is moved to the front of *SPLST*. Since many respellings are of the type with no disagreements, this procedure has the effect of considerably reducing the time required to correct the spelling of frequently misspelled words.

### 20.7.1 Synonyms

Spelling lists also provide a way of defining synonyms for a particular context. If a dotted pair appears on a spelling list (instead of just an atom), CAR is interpreted as the correct spelling of the misspelled word, and CDR as the antecedent for that word. If CAR is identical with the misspelled word, the antecedent is returned without any interaction or approval being necessary. If the misspelled word corrects to CAR of the dotted pair, the usual interaction and approval will take place, and then the antecedent, i.e., CDR of the dotted pair, is returned. For example, the user could make IFLG synonymous with CLISPIFTRANFLG by adding (IFLG . CLISPIFTRANFLG) to SPELLINGS3, the spelling list for unbound atoms. Similarly, the user could make OTHERWISE mean the same as ELSEIF by adding (OTHERWISE . ELSEIF) to CLISPIFWORDSPLST, or make L be synonymous with LAMBDA by adding (L . LAMBDA) to LAMBDASPLST. Note that L could also be used as a variable without confusion, since the association of L with LAMBDA occurs only in the appropriate context.

### 20.7.2 Spelling Lists

Any list of atoms can be used as a spelling list, e.g., BROKENFNS, FILELST, etc. Various system packages have their own spellings lists, e.g., LISPXCOMS, CLISPFORWORDSPLST, EDITCOMSA, etc. These are documented under their corresponding sections, and are also indexed under "spelling lists." In addition to these spelling lists, the system maintains, i.e., automatically adds to, and occasionally prunes, four lists used solely for spelling correction: SPELLINGS1, SPELLINGS2, SPELLINGS3, and USERWORDS. These spelling lists are maintained only when ADDSPELLFLG is non-NIL. ADDSPELLFLG is initially T.

#### SPELLINGS1

[Variable]

SPELLINGS1 is a list of functions used for spelling correction when an input is typed in apply format, and the function is undefined, e.g., EDTIF(FOO). SPELLINGS1 is initialized to contain DEFINEQ, BREAK, MAKEFILE, EDITF, TCOMPL, LOAD, etc. Whenever LISPX is given an input in apply format, i.e., a function and arguments, the name of the function is added to SPELLINGS1 if the function has a definition.

For example, typing CALLS(EDITF) will cause CALLS to be added to SPELLINGS1. Thus if the user typed CALLS(EDITF) and later typed CALLS(EDITV), since SPELLINGS1 would then contain CALLS, DWIM would be successful in correcting CALLS to CALLS.

#### SPELLINGS2

[Variable]

SPELLINGS2 is a list of functions used for spelling correction for all other undefined functions. It is initialized to contain functions such as ADD1, APPEND, COND, CONS, GO, LIST, NCONC, PRINT, PROG, RETURN, SETQ, etc. Whenever LISPX is given a non-atomic form, the name of the function is added to SPELLINGS2. For example, typing (RETFROM (STKPOS (QUOTE FOO) 2)) to a break would add RETFROM to SPELLINGS2. Function names are also added to SPELLINGS2 by DEFINE, DEFINEQ, LOAD (when loading compiled code), UNSAVEDEF, EDITF, and PRETTYPRINT.

#### SPELLINGS3

[Variable]

SPELLINGS3 is a list of words used for spelling correction on all unbound atoms. SPELLINGS3 is initialized to EDITMACROS, BREAKMACROS, BROKENFNS, and ADVISEDFNS. Whenever LISPX is given an atom to evaluate, the name of the atom is added to SPELLINGS3 if the atom has a value. Atoms are also added to SPELLINGS3 whenever they are edited by EDITV, and whenever they are set via RPAQ or RPAQQ. For example, when a file is loaded, all of the variables set in the file are added to SPELLINGS3. Atoms are also added to SPELLINGS3 when they are set by a LISPX input, e.g., typing (SETQ FOO (REVERSE (SETQ FIE ...))) will add both FOO and FIE to SPELLINGS3.

#### **USERWORDS**

[Variable]

USERWORDS is a list containing both functions and variables that the user has referred to, e.g., by breaking or editing. USERWORDS is used for spelling correction by ARGLIST, UNSAVEDEF, PRETTYPRINT, BREAK, EDITF, ADVISE, etc. USERWORDS is initially NIL. Function names are added to it by DEFINE, DEFINEQ, LOAD, (when loading compiled code, or loading exprs to property lists) UNSAVEDEF, EDITF, EDITV, EDITP, PRETTYPRINT, etc. Variable names are added to USERWORDS at the same time as they are added to SPELLINGS3. In addition, the

variable LASTWORD is always set to the last word added to USERWORDS, i.e., the last function or variable referred to by the user, and the respelling of NIL is defined to be the value of LASTWORD. Thus, if the user has just defined a function, he can then prettyprint it by typing PP().

Each of the above four spelling lists are divided into two sections separated by a special marker (the value of the variable SPELLSTR1). The first section contains the "permanent" words; the second section contains the temporary words. New words are added to the corresponding spelling list at the front of its temporary section (except that functions added to SPELLINGS1 or SPELLINGS2 by LISPX are always added to the end of the permanent section. If the word is already in the temporary section, it is moved to the front of that section; if the word is in the permanent section, no action is taken. If the length of the temporary section then exceeds a specified number, the last (oldest) word in the temporary section is forgotten, i.e., deleted. This procedure prevents the spelling lists from becoming cluttered with unimportant words that are no longer being used, and thereby slowing down spelling correction time. Since the spelling corrector usually moves each word selected as a respelling to the front of its spelling list, the word is thereby moved into the permanent section. Thus once a word is misspelled and corrected, it is considered important and will never be forgotten.

Note: The spelling correction algorithm will not alter a spelling list unless it contains the special marker (the value of SPELLSTR1). This provides a way to ensure that a spelling list will not be altered.

#SPELLINGS1	[Variable]
#SPELLINGS2	[Variable]
#SPELLINGS3	[Variable]
#USERWORDS	(Variable)

The maximum length of the temporary section for SPELLINGS1, SPELLINGS2, SPELLINGS3 and USERWORDS is given by the value of #SPELLINGS1, #SPELLINGS2, #SPELLINGS3, and #USERWORDS, initialized to 30, 30, 30, and 60 respectively.

Users can alter these values to modify the performance behavior of spelling correction.

20.18

### 20.7.3 Generators for Spelling Correction

For some applications, it is more convenient to *generate* candidates for a respelling one by one, rather than construct a complete list of all possible candidates, e.g., spelling correction involving a large directory of files, or a natural language data base. For these purposes, *SPLST* can be an array (of any size). The first element of this array is the generator function, which is called with the array itself as its argument. Thus the function can use the remainder of the array to store "state" information, e.g., the last position on a file, a pointer into a data structure, etc. The value returned by the function is the next candidate for respelling. If **NIL** is returned, the spelling "list" is considered to be exhausted, and the closest match is returned. If a candidate is found with no disagreements, it is returned immediately without waiting for the "list" to exhaust.

SPLST can also be a generator, i.e. the value of the function GENERATOR (page 11.17). The generator SPLST will be started up whenever the spelling corrector needs the next candidate, and it should return candidates via the function PRODUCE. For example, the following could be used as a "spelling list" which effectively contains all functions in the system:

### [GENERATOR

(MAPATOMS (FUNCTION (LAMBDA (X) (if (GETD X) then (PRODUCE X]

### 20.7.4 Spelling Corrector Algorithm

The basic philosophy of DWIM spelling correction is to count the number of disagreements between two words, and use this number divided by the length of the longer of the two words as a measure of their relative disagreement. One minus this number is then the relative agreement or closeness. For example, CONS and CONX differ only in their last character. Such substitution errors count as one disagreement, so that the two words are in 75% agreement. Most calls to the spelling corrector specify a relative agreement of 70, so that a single substitution error is permitted in words of four characters or longer. However, spelling correction on shorter words is possible since certain types of differences such as single transpositions are not counted as disagreements. For example, AND and NAD have a relative agreement of 100. Calls to the spelling corrector from DWIM use the value of FIXSPELLREL, which is initially 70. Note that by setting FIXSPELLREL to 100, only spelling corrections with "zero" mistakes, will be considered, e.g., transpositions, double characters, etc.

The central function of the spelling corrector is CHOOZ. CHOOZ takes as arguments: a word, a minimum relative agreement, a

DWIM

spelling list, and an optional functional argument, XWORD, REL, SPLST, and FN respectively.

CHOOZ proceeds down SPLST examining each word. Words not satisfying FN (if FN is non-NIL), or those obviously too long or too short to be sufficiently close to XWORD are immediately rejected. For example, if REL = 70, and XWORD is 5 characters long, words longer than 7 characters will be rejected.

Special treatment is necessary for words shorter than XWORD, since doubled letters are not counted as disagreements. For example, CONNSSS and CONS have a relative agreement of 100. CHOOZ handles this by counting the number of doubled characters in XWORD before it begins scanning SPLST, and taking this into account when deciding whether to reject shorter words.

If TWORD, the current word on SPLST, is not rejected, CHOOZ computes the number of disagreements between it and XWORD by calling a subfunction, SKOR.

SKOR operates by scanning both words from left to right one character at a time. SKOR operates on the list of character codes for each word. This list is computed by CHOOZ before calling SKOR. Characters are considered to agree if they are the same characters or appear on the same key (i.e., a shift mistake). The variable SPELLCASEARRAY is a CASEARRAY which is used to determine equivalence classes for this purpose. It is initialized to equivalence lowercase and upper case letters, as well as the standard key transitions: for example, 1 with !, 3 with #, etc.

If the first character in XWORD and TWORD do not agree, SKOR checks to see if either character is the same as one previously encountered, and not accounted-for at that time. (In other words, transpositions are not handled by lookahead, but by lookback.) A displacement of two or fewer positions is counted as a transposition; a displacement by more than two positions is counted as a disagreement. In either case, both characters are now considered as accounted for and are discarded, and SKORing continues.

If the first character in XWORD and TWORD do not agree, and neither agree with previously unaccounted-for characters, and TWORD has more characters remaining than XWORD, SKOR removes and saves the first character of TWORD, and continues by comparing the rest of TWORD with XWORD as described above. If TWORD has the same or fewer characters remaining than XWORD, the procedure is the same except that the character is removed from XWORD. In this case, a special check is first made to see if that character is equal to the previous character in XWORD, or to the next character in XWORD, i.e., a double character typo, and if so, the character is considered accounted-for, and not counted as a disagreement. In this case,

the "length" of XWORD is also decremented. Otherwise making XWORD sufficiently long by adding double characters would make it be arbitrarily close to TWORD, e.g., XXXXXX would correct to PP.

When SKOR has finished processing both XWORD and TWORD in this fashion, the value of SKOR is the number of unaccounted-for characters, plus the number of disagreements, plus the number of tranpositions, with two qualifications: (1) if both XWORD and TWORD have a character unaccounted-for in the same position, the two characters are counted only once, i.e., substitution errors count as only one disagreement, not two; and (2) if there are no unaccounted-for characters and disagreements, no transpositions are not counted. This permits spelling correction on very short words, such as edit commands, e.g., XRT->XTR. Transpositions are also not counted when FASTYPEFLG = T, for example, IPULX and IPLUS will be in 80% agreement with FASTYPEFLG = T, only 60% with FASTYPEFLG = NIL. The rationale behind this is that transpositions are much more common for fast typists, and should not be counted as disagreements, whereas more deliberate typists are not as likely to combine tranpositions and other mistakes in a single word, and therefore can use more conservative metric. FASTYPEFLG is initially NIL.

### 20.7.5 Spelling Corrector Functions and Variables

#### (ADDSPELL X SPLST N)

[Function]

Adds X to one of the spelling lists as determined by the value of SPLST:

NIL Adds X to USERWORDS and to SPELLINGS2. Used by DEFINEQ.

- **0** Adds *X* to **USERWORDS**. Used by **LOAD** when loading **EXPRs** to property lists.
- 1 Adds X to SPELLINGS1 (at end of permanent section). Used by LISPX.
- 2 Adds X to SPELLINGS2 (at end of permanent section). Used by LISPX.
- 3 Adds X to USERWORDS and SPELLINGS3.

#### a spelling list

If *SPLST* is a spelling list, *X* is added to it. In this case, *N* is the (optional) length of the temporary section.

If X is already on the spelling list, and in its temporary section, ADDSPELL moves X to the front of that section.

ADDSPELL sets LASTWORD to X when SPLST = NIL, 0 or 3.

If X is not a literal atom, ADDSPELL takes no action.

DWIM

Note that the various systems calls to ADDSPELL, e.g. from DEFINE, EDITF, LOAD, etc., can all be suppressed by setting or binding ADDSPELLFLG to NIL (page 20.13).

#### (MISSPELLED? XWORD REL SPLST FLG TAIL FN)

[Function]

If XWORD = NIL or \$ (<esc>), MISSPELLED? prints = followed by the value of LASTWORD, and returns this as the respelling, without asking for approval. Otherwise, MISSPELLED? checks to see if XWORD is really misspelled, i.e., if FN applied to XWORD is true, or XWORD is already contained on SPLST. In this case, MISSPELLED? simply returns XWORD. Otherwise MISSPELLED? computes and returns (FIXSPELL XWORD REL SPLST FLG TAIL FN).

#### (FIXSPELL XWORD REL SPLST FLG TAIL FN TIEFLG DONTMOVETOPFLG — —) [Function]

The value of FIXSPELL is either the respelling of XWORD or NIL. If for some reason XWORD itself is on SPLST, then FIXSPELL aborts and calls ERROR!. If there is a possibility that XWORD is spelled correctly, MISSPELLED? should be used instead of FIXSPELL. FIXSPELL performs all of the interactions described earlier, including requesting user approval if necessary.

If XWORD = NIL or \$ (escape), the respelling is the value of LASTWORD, and no approval is requested.

If XWORD contains lowercase characters, and the corresponding uppercase word is correct, i.e. on SPLST or satisfies FN, the uppercase word is returned and no interaction is performed. If FIXSPELL.UPPERCASE.QUIET is NIL (the default), a warning "=XX" is printed when coercing from "xx" to "XX". If FIXSPELL.UPPERCASE.QUIET is non-NIL, no warning is given.

If REL = NIL, defaults to the value of FIXSPELLREL (initially 70).

If FLG = NIL, the correction is handled in type-in mode, i.e., approval is never requested, and XWORD is not typed. If FLG = T, XWORD is typed (before the =) and approval is requested if APPROVEFLG = T. If FLG = NO-MESSAGE, the correction is returned with no further processing. In this case, a run-on correction will be returned as a dotted pair of the two parts of the word, and a synonym correction as a list of the form (WORD1 WORD2), where WORD1 is (the corrected version of) XWORD, and WORD2 is the synonym. Note that the effect of the function CHOOZ can be obtained by calling FIXSPELL with FLG = NO-MESSAGE

If *TAIL* is not **NIL**, and the correction is successful, **CAR** of *TAIL* is replaced by the respelling (using /RPLACA).

FIXSPELL will attempt to correct misspellings caused by running two words together, if the global variable RUNONFLG is non-NIL (default is NIL). In this case, approval is always requested. When a run-on error is corrected, CAR of TAIL is replaced by the two

words, and the value of FIXSPELL is the first one. For example, if FIXSPELL is called to correct the edit command (MOVE TO AFTERCOND 3 2) with TAIL = (AFTERCOND 3 2), TAIL would be changed to (AFTER COND 2 3), and FIXSPELL would return AFTER (subject to user approval where necessary). If TAIL = T, FIXSPELL will also perform run-on corrections, returning a dotted pair of the two words in the event the correction is of this type.

If TIEFLG = NIL and a tie occurs, i.e., more than one word on SPLST is found with the same degree of "closeness", FIXSPELL returns NIL, i.e., no correction. If TIEFLG = PICKONE and a tie occurs, the first word is taken as the correct spelling. If TIEFLG = LIST, the value of FIXSPELL is a list of the respellings (even if there is only one), and FIXSPELL will not perform any interaction with the user, nor modify TAIL, the idea being that the calling program will handle those tasks. Similarly, if TIEFLG = EVERYTHING, a list of all candidates whose degree of closeness is above REL will be returned, regardless of whether some are better than others. No interaction will be performed.

If DONTMOVETOPFLG = T and a correction occurs, it will not be moved to the front of the spelling list. Also, the spelling list will not be altered unless it contains the special marker used to separate the temporary and perminant parts of the system spelling lists (the value of SPELLSTR1).

#### (FNCHECK FN NOERRORFLG SPELLFLG PROPFLG TAIL)

[Function]

The task of FNCHECK is to check whether FN is the name of a function and if not, to correct its spelling. If FN is the name of a function or spelling correction is successful, FNCHECK adds the (corrected) name of the function to USERWORDS using ADDSPELL, and returns it as its value.

Since FNCHECK is called by many low level functions such as ARGLIST, UNSAVEDEF, etc., spelling correction only takes place when DWIMFLG = T, so that these functions can operate in a small Interlisp system which does not contain DWIM.

**NOERRORFLG** informs **FNCHECK** whether or not the calling function wants to handle the unsuccessful case: if **NOERRORFLG** is **T, FNCHECK** simply returns **NIL**, otherwise it prints **fn NOT** A **FUNCTION** and generates a non-breaking error.

If FN does not have a definition, but does have an EXPR property, then spelling correction is not attempted. Instead, if PROPFLG = T, FN is considered to be the name of a function, and is returned. If PROPFLG = NIL, FN is not considered to be the name of a function, and NIL is returned or an error generated, depending on the value of NOERRORFLG.

**FNCHECK** calls **MISSPELLED?** to perform spelling correction, so that if FN = NIL, the value of **LASTWORD** will be returned.

SPELLFLG corresponds to MISSPELLED?'s fourth argument, FLG. If SPELLFLG = T, approval will be asked if DWIM was enabled in CAUTIOUS mode, i.e., if APPROVEFLG = T. TAIL corresponds to the fifth argument to MISSPELLED?.

FNCHECK is currently used by ARGLIST, UNSAVEDEF, PRETTYPRINT, BREAKO, BREAKIN, ADVISE, and CALLS. For example, BREAKO calls FNCHECK with NOERRORFLG = T since if FNCHECK cannot produce a function, BREAKO wants to define a dummy one. CALLS however calls FNCHECK with NOERRORFLG = NIL, since it cannot operate without a function.

Many other system functions call MISSPELLED? or FIXSPELL directly. For example, BREAK1 calls FIXSPELL on unrecognized atomic inputs before attempting to evaluate them, using as a spelling list a list of all break commands. Similarly, LISPX calls FIXSPELL on atomic inputs using a list of all LISPX commands. When UNBREAK is given the name of a function that is not broken, it calls FIXSPELL with two different spelling lists, first with BROKENFNS, and if that fails, with USERWORDS. MAKEFILE calls MISSPELLED? using FILELST as a spelling list. Finally, LOAD, BCOMPL, BRECOMPILE, TCOMPL, and RECOMPILE all call MISSPELLED? if their input file(s) won't open.

TOC. 2 TABLE OF CONTENTS

The syntax of Lisp is very simple, in the sense that it can be described concisely, but not in the sense that Lisp programs are easy to read or write! This simplicity of syntax is achieved by, and at the expense of, extensive use of explicit structuring, namely grouping through parenthesization. Unlike many languages, there are no reserved words in Lisp such as IF, THEN, FOR, DO, etc., nor reserved characters like +, -, =,  $\leftarrow$ , etc. The only special characters are left and right parentheses and period, which are used for indicating structure, and space and end-of-line, which are used for delimiting identifiers. This eliminates entirely the need for parsers and precedence rules in the Lisp interpreter and compiler, and thereby makes program manipulation of Lisp programs straightforward. In other words, a program that "looks at" other Lisp programs does not need to incorporate a lot of syntactic information. For example, a Lisp interpreter can be written in one or two pages of Lisp code. It is for this reason that Lisp is by far the most suitable, and frequently used, programming language for writing programs that deal with other programs as data, e.g., programs that analyze, modify, or construct other programs.

However, it is precisely this same simplicity of syntax that makes Lisp programs difficult to read and write (especially for beginners). 'Pushing down' is something programs do very well, and people do poorly. As an example, consider the following two "equivalent" sentences:

"The rat that the cat that the dog that I owned chased caught ate the cheese."

#### versus

"I own the dog that chased the cat that caught the rat that ate the cheese."

Natural language contains many linguistic devices such as that illustrated in the second sentence above for minimizing embedding, because embedded sentences are more difficult to grasp and understand than equivalent non-embedded ones (even if the lawer sentences are somewhat longer). Similarly, most high level programming languages offer syntactic devices for reducing apparent depth and complexity of a program: the reserved words and infix operators used in ALGOL-like languages simultaneously delimit operands and operations, and also convey meaning to the programmer. They are far more intuitive than parentheses. In fact, since Lisp uses parentheses (i.e., lists)

for almost all syntactic forms, there is very little information contained in the parentheses for the person reading a Lisp program, and so the parentheses tend mostly to be ignored: the meaning of a particular Lisp expression for people is found almost entirely in the words, not in the structure. For example, the expression

#### (COND (EQ N 0) 1) (T TIMES N FACTORIAL ((SUB1 N)))

is recognizable as factorial even though there are five misplaced or missing parentheses. Grouping words together in parentheses is done more for Lisp's benefit, than for the programmer's.

CLISP is designed to make Interlisp programs easier to read and write by permitting the user to employ various infix operators, IF statements (page 9.5), and iterative statements (page 9.9), which are automatically converted to equivalent Interlisp expressions when they are first interpreted. For example, factorial could be written in CLISP:

#### (IF N = 0 THEN 1 ELSE N\*(FACTORIAL N-1))

Note that this expression would become an equivalent COND after it had been interpreted once, so that programs that might have to analyze or otherwise process this expression could take advantage of the simple syntax.

There have been similar efforts in other Lisp systems. CLISP differs from these in that it does not attempt to replace the Lisp syntax so much as to augment it. In fact, one of the principal criteria in the design of CLISP was that users be able to freely intermix Lisp and CLISP without having to identify which is which. Users can write programs, or type in expressions for evaluation, in Lisp, CLISP, or a mixture of both. In this way, users do not have to learn a whole new language and syntax in order to be able to use selected facilities of CLISP when and where they find them useful.

CLISP is implemented via the error correction machinery in Interlisp (see page 20.1). Thus, any expression that is well-formed from Interlisp's standpoint will never be seen by CLISP (i.e., if the user defined a function IF, he would effectively turn off that part of CLISP). This means that interpreted programs that do not use CLISP constructs do not pay for its availability by slower execution time. In fact, the Interlisp interpreter does not "know" about CLISP at all. It operates as before, and when an erroneous form is encountered, the interpreter calls an error routine which in turn invokes the Do-What-I-Mean (DWIM) analyzer which contains CLISP. If the expression in question turns out to be a CLISP construct, the equivalent Interlisp form is returned to the interpreter. In addition, the original CLISP expression, is modified so that it

becomes the correctly translated Interlisp form. In this way, the analysis and translation are done only once.

Integrating CLISP into the Interlisp system (instead of, for example, implementing it as a separate preprocessor) makes possible Do-What-I-Mean features for CLISP constructs as well as for pure Lisp expressions. For example, if the user has defined a function named GET-PARENT, CLISP would know not to attempt to interpret the form (GET-PARENT) as an arithmetic infix operation. (Actually, CLISP would never get to see this form, since it does not contain any errors.) If the user mistakenly writes (GET-PRAENT), CLISP would know he meant (GET-PARENT), and not (DIFFERENCE GET PRAENT), by using the information that PRAENT is not the name of a variable, and that GET-PARENT is the name of a user function whose spelling is "very close" to that of GET-PRAENT. Similarly, by using information about the program's environment not readily available to a preprocessor, CLISP can successfully resolve the following sorts of ambiguities:

- (1) (LIST X\*FACT N), where FACT is the name of a variable, means (LIST (X\*FACT) N).
- (2) (LIST X\*FACT N), where FACT is not the name of a variable but instead is the name of a function, means (LIST X\*(FACT N)), i.e., N is FACT's argument.
- (3) (LIST X\*FACT(N)), FACT the name of a function (and not the name of a variable), means (LIST X\*(FACT N)).
- (4) cases (1), (2) and (3) with FACT misspelled!

The first expression is correct both from the standpoint of CLISP syntax and semantics and the change would be made without the user being notified. In the other cases, the user would be informed or consulted about what was taking place. example, to take an extreme case, suppose the expression (LIST X\*FCCT N) were encountered, where there was both a function named FACT and a variable named FCT. The user would first be asked if FCCT were a misspelling of FCT. If he said YES, the expression would be interpreted as (LIST (X\*FCT) N). If he said NO, the user would be asked if FCCT were a misspelling of FACT, i.e., if he intended X\*FCCT N to mean X\*(FACT N). If he said YES to this question, the indicated transformation would be performed. If he said NO, the system would then ask if X\*FCCT should be treated as CLISP, since FCCT is not the name of a (bound) variable. If he said YES, the expression would be transformed, if NO, it would be left alone, i.e., as (LIST X\*FCCT N). Note that we have not even considered the case where X\*FCCT is itself a misspelling of a variable name, e.g., a variable named XFCT (as with GET-PRAENT). This sort of transformation would be considered after the user said NO to X\*FCCT N -> X\*(FACT N).

CLISP

The question of whether X\*FCCT should be treated as CLISP is important because Interlisp users may have programs that employ identifiers containing CLISP operators. Thus, if CLISP encounters the expression A/B in a context where either A or B are not the names of variables, it will ask the user if A/B is intended to be CLISP, in case the user really does have a free variable named A/B.

Note: Through the discussion above, we speak of CLISP or DWIM asking the user. Actually, if the expression in question was typed in by the user for immediate execution, the user is simply informed of the transformation, on the grounds that the user would prefer an occasional misinterpretation rather than being continuously bothered, especially since he can always retype what he intended if a mistake occurs, and ask the programmer's assistant to UNDO the effects of the mistaken operations if necessary. For transformations on expressions in user programs, the user can inform CLISP whether he wishes to operate in CAUTIOUS or TRUSTING mode. In the former case (most typical) the user will be asked to approve transformations, in the latter, CLISP will operate as it does on type-in, i.e., perform the transformation after informing the user.

CLISP can also handle parentheses errors caused by typing 8 or 9 for "(" or ")". (On most terminals, 8 and 9 are the lower case characters for "(" and ")", i.e., "(" and 8 appear on the same key, as do ")" and 9.) For example, if the user writes N\*8FACTORIAL N-1, the parentheses error can be detected and fixed before the infix operator \* is converted to the Interlisp function TIMES. CLISP is able to distinguish this situation from cases like N\*8\*X meaning (TIMES N 8 X), or N\*8X, where 8X is the name of a variable, again by using information about the programming environment. In fact, by integrating CLISP with DWIM, CLISP has been made sufficiently tolerant of errors that almost everything can be misspelled! For example, CLISP can successfully translate the definition of FACTORIAL:

#### (IFF N = 0 THENN1 ESLE N\*8FACTTORIALNN-1)

to the corresponding COND, while making 5 spelling corrections and fixing the parenthesis error. CLISP also contains a facility for converting from Interlisp back to CLISP, so that after running the above incorrect definition of FACTORIAL, the user could "clispify" the now correct version to obtain (IF N = 0 THEN 1 ELSE  $N^*(FACTORIAL N-1)$ ).

This sort of robustness prevails throughout CLISP. For example, the iterative statement permits the user to say things like:

#### (FOR OLD X FROM M TO N DO (PRINT X) WHILE (PRIMEP X))

However, the user can also write OLD ( $X \leftarrow M$ ), (OLD  $X \leftarrow M$ ), (OLD ( $X \leftarrow M$ )), permute the order of the operators, e.g., (DO PRINT X TO N FOR OLD  $X \leftarrow M$  WHILE PRIMEP X), omit either or both sets

of parentheses, misspell any or all of the operators FOR, OLD, FROM, TO, DO, or WHILE, or leave out the word DO entirely! And, of course, he can also misspell PRINT, PRIMEP, M or N! In this example, the only thing the user could not misspell is the first X, since it specifies the *name* of the variable of iteration. The other two instances of X could be misspelled.

CLISP is well integrated into the Interlisp system. For example, the above iterative statement translates into an following equivalent Interlisp form using PROG, COND, GO, etc. When the interpreter subsequently encounters this CLISP expression, it automatically obtains and evaluates the translation. Similarly, the compiler "knows" to compile the translated form. However, if the user PRETTYPRINTs his program, PRETTYPRINT "knows" to print the original CLISP at the corresponding point in his function. Similarly, when the user edits his program, the editor keeps the translation invisible to the user. If the user modifies the CLISP, the translation is automatically discarded and recomputed the next time the expression is evaluated.

In short, CLISP is not a language at all, but rather a system. It plays a role analogous to that of the programmer's assistant (page 13.1). Whereas the programmer's assistant is an invisible intermediary agent between the user's console requests and the Interlisp executive, CLISP sits between the user's programs and the Interlisp interpreter.

Only a small effort has been devoted to defining the core syntax of CLISP. Instead, most of the effort has been concentrated on providing a facility which "makes sense" out of the input expressions using context information as well as built-in and acquired information about user and system programs. It has been said that communication is based on the intention of the speaker to produce an effect in the recipient. CLISP operates under the assumption that what the user said was intended to represent a meaningful operation, and therefore tries very hard to make sense out of it. The motivation behind CLISP is not to provide the user with many different ways of saying the same thing, but to enable him to worry less about the syntactic aspects of his communication with the system. In other words, it gives the user a new degree of freedom by permitting him to concentrate more on the problem at hand, rather than on translation into a formal and unambiguous language.

DWIM and CLISP are invoked on iterative statements because CAR of the iterative statement is not the name of a function, and hence generates an error. If the user defines a function by the same name as an i.s. operator, e.g., WHILE, TO, etc., the operator will no longer have the CLISP interpretation when it appears as CAR of a form, although it will continue to be treated as an i.s. operator if it appears in the interior of an i.s. To alert the user, a

warning message is printed, e.g., (WHILE DEFINED, THEREFORE DISABLED IN CLISP).

#### 21.1 CLISP Interaction with User

Syntactically and semantically well formed CLISP transformations are always performed without informing the user. Other CLISP transformations described in the previous section, e.g., misspellings of operands, infix operators, parentheses errors, unary minus - binary minus errors, all follow the same protocol as other DWIM transformations (page 20.1). That is, if DWIM has been enabled in TRUSTING mode, or the transformation is in an expression typed in by the user for immediate execution, user approval is not requested, but the user is informed. However, if the transformation involves a user program, and DWIM was enabled in CAUTIOUS mode, the user will be asked to approve. If he says NO, the transformation is not performed. Thus, in the previous section, phrases such as "one of these (transformations) succeeds" and "the transformation LAST-ELL -> LAST-EL would be found" etc., all mean if the user is in CAUTIOUS mode and the error is in a program, the corresponding transformation will be performed only if the user approves (or defaults by not responding). If the user says NO, the procedure followed is the same as though the transformation had not been found. For example, if A\*B appears in the function FOO, and B is not bound (and no other transformations are found) the user would be asked A\*B [IN FOO] TREAT AS CLISP? (The waiting time on such interactions is three times as long as for simple corrections, i.e., 3\*DWIMWAIT).

In certain situations, DWIM will ask for approval even if DWIM is enabled in TRUSTING mode. For example, the user will always be asked to approve a spelling correction that might also be interpreted as a CLISP transformation, as in LAST-ELL -> LAST-EL.

If the user approved, A\*B would be transformed to (ITIMES A B), which would then cause a U.B.A. B error in the event that the program was being run (remember the entire discussion also applies to DWIMIFYing). If the user said NO, A\*B would be left alone.

If the value of CLISPHELPFLG = NIL (initally T), the user will not be asked to approve any CLISP transformation. Instead, in those situations where approval would be required, the effect is the same as though the user had been asked and said NO.

## 21.2 CLISP Character Operators

CLISP recognizes a number of special characters operators, both prefix and infix, which are translated into common expressions. For example, the character + is recognized to represent addition, so CLISP translates the litatom A + B to the form (IPLUS A B). Note that CLISP is envoked, and this translation is made, only if an error occurs, such as an unbound atom error or an undefined function error for the perfectly legitamate litatom A + B. Therefore the user may choose not to use these facilities with no penalty, similar to other CLISP facilities.

The user has a lot of flexability in using CLISP character operators. A list, can always be substituted for a litatom, and vice versa, without changing the interpretation of a phrase. For example, if the value of (FOO X) is A, and the value of (FIE Y) is B, then (LIST (FOO X) + (FIE Y)) has the same value as (LIST A + B). Note that the first expression is a list of four elements: the atom "LIST", the list "(FOO X)", the atom " + ", and the list "(FIE X)", whereas the second expression, (LIST A + B), is a list of only two elements: the litatom "LIST" and the litatom "A + B". Since (LIST (FOO X) + (FIE Y)) is indistinguishable from (LIST (FOO X) + (FIE Y)) because spaces before or after parentheses have no effect on the Interlisp READ program, to be consistent, extra spaces have no effect on atomic operands either. In other words, CLISP will treat (LIST A + B), (LIST A + B), and (LIST A + B) the same as (LIST A + B).

Note: CLISP does not use its own special READ program because this would require the user to explicitly identify CLISP expressions, instead of being able to intermix Interlisp and CLISP.

+	[CLISP Operator]
•	[CLISP Operator]
*	[CLISP Operator]
1	[CLISP Operator]
<b>↑</b>	[CLISP Operator]
	CLISP recognizes + - * / and 1 as the normal arithmetic infiv

CLISP recognizes +,-,\*,/, and ↑ as the normal arithmetic infix operators. - is also recognized as the prefix operator, unary minus. These are converted to PLUS, DIFFERENCE (or in the case of unary minus, MINUS), TIMES, QUOTIENT, and EXPT.

Normally, CLISP uses the "generic" arithmetic functions PLUS, TIMES, etc. CLISP contains a facility for declaring which type of arithmetic is to be used, either by making a global declaration, or

CLISP

by separate declarations about individual functions or variables (see page 21.12).

The usual precedence rules apply (although these can be easily changed by the user), i.e., \* has higher precedence than + so that  $A + B \cdot C$  is the same as  $A + (B \cdot C)$ , and both \* and / are lower than  $\uparrow$  so that  $2 \cdot X \uparrow 2$  is the same as  $2 \cdot (X \uparrow 2)$ . Operators of the same precedence group from left to right, e.g., A/B/C is equivalent to (A/B)/C. Minus is binary whenever possible, i.e., except when it is the first operator in a list, as in (-A) or (-A), or when it immediately follows another operator, as in  $A \cdot -B$ . Note that grouping with parentheses can always be used to override the normal precedence grouping, or when the user is not sure how a particular expression will parse. The complete order of precedence for CLISP operators is given below.

Note that + in front of a number will disappear when the number is read, e.g., (FOO X + 2) is indistinguishable from (FOO X 2). This means that (FOO X + 2) will not be interpreted as CLISP, or be converted to (FOO (IPLUS X 2)). Similarly, (FOO X - 2) will not be interpreted the same as (FOO X-2). To circumvent this, always type a space between the + or - and a number if an infix operator is intended, e.g., write (FOO X + 2).

=	[CLISP Operator]
GT	[CLISP Operator]
LT	[CLISP Operator]
GE	[CLISP Operator]
LE	[CLISP Operator]

These are infix operators for "Equal", "Greater Than", "Less Than", "Greater Than or Equal", and "Less Than or Equal".

**GT**, **LT**, **GE**, and **LE** are all affected by the same declarations as + and \*, with the initial default to use **GREATERP** and **LESSP**.

Note that only single character operators, e.g., +,  $\leftarrow$ , =, etc., can appear in the *interior* of an atom. All other operators must be set off from identifiers with spaces. For example, XLTY will not be recognized as CLISP. In some cases, DWIM will be able to diagnose this situation as a run-on spelling error, in which case after the atom is split apart, CLISP will be able to perform the indicated transformation.

A number of lisp functions, such as EQUAL, MEMBER, AND, OR, etc., can also be treated as CLISP infix operators. New infix

21.8

operators can be easily added (see page 21.27). Spelling correction on misspelled infix operators is performed using CLISPINFIXSPLST as a spelling list.

AND is higher than OR, and both AND and OR are lower than the other infix operators, so (X OR Y AND Z) is the same as (X OR (Y AND Z)), and (X AND Y EQUAL Z) is the same as (X AND (Y EQUAL Z)). All of the infix predicates have lower precedence than Interlisp forms, since it is far more common to apply a predicate to two forms, than to use a Boolean as an argument to a function. Therefore, (FOO X GT FIE Y) is translated as ((FOO X) GT (FIE Y)), rather than as (FOO (X GT (FIE Y))). However, the user can easily change this.

[CLISP Operator]

X:N extracts the Nth element of the list X. FOO:3 specifies the third element of FOO, or (CADDR FOO). If N is less than zero, this indicates elements counting from the end of the list; i.e. FOO:-1 is the last element of FOO. : operators can be nested, so FOO:1:2 means the second element of the first element of FOO, or (CADAR FOO).

The: operator can also be used for extracting substructures of records (see page 8.1). Record operations are implemented by replacing expressions of the form X:FOO by (fetch FOO of X). Both lower and upper case are acceptable.

: is also used to indicate operations in the pattern match facility (page 12.24). X:(&'A -- 'B) translates to (match X with (&'A -- 'B))

[CLISP Operator]

In combination with:, a period can be used to specify the "data path" for record operations. For example, if FOO is a field of the BAR record, X:BAR.FOO is translated into (fetch (BAR FOO) of X). Subrecord fields can be specified with multiple periods: X:BAR.FOO.BAZ translates into (fetch (BAR FOO BAZ) of X).

Note: If a record contains fields with periods in them, CLISPIFY will not translate a record operation into a form using periods to specify the data path. For example, CLISPIFY will NOT translate (fetch A.B of X) into X:A.B.

[CLISP Operator]

X:N, returns the Nth tail of the list X. For example, FOO::3 is (CDDDR FOO), and FOO::-1 is (LAST FOO).

[CLISP Operator]

← is used to indicate assignment. For example, X←Y translates to (SETQ X Y). If X does not have a value, and is not the name of one of the bound variables of the function in which it appears,

spelling correction is attempted. However, since this may simply be a case of assigning an initial value to a new free variable, DWIM will always ask for approval before making the correction.

In conjunction with: and::, ← can also be used to perform a more general type of assignment, involving structure modification. For example, X:2←Y means "make the second element of X be Y", in Interlisp terms (RPLACA (CDR X) Y). Note that the *value* of this operation is the value of RPLACA, which is (CDR X), rather than Y. Negative numbers can also be used, e.g., X:-2←Y, which translates to (RPLACA (NLEFT X 2) Y).

The user can indicate he wants /RPLACA and /RPLACD used (undoable version of RPLACA and RPLACD, see page 13.26), or FRPLACA and FRPLACD (fast versions of RPLACA and RPLACD, see page 3.3), by means of CLISP declarations (page 21.12). The initial default is to use RPLACA and RPLACD.

← is also used to indicate assignment in record operations (X:FOO←Y translates to (replace FOO of X with Y).), and pattern match operations (page 12.24).

 $\leftarrow$  has different precedence on the left from on the right. On the left,  $\leftarrow$  is a "tight" operator, i.e., high precedence, so that  $A + B \leftarrow C$  is the same as  $A + (B \leftarrow C)$ . On the right,  $\leftarrow$  has broader scope so that  $A \leftarrow B + C$  is the same as  $A \leftarrow (B + C)$ .

On typein, \$\(\infty\)FORM (where \$\(\text{is}\) is equivalent to set the "last thing mentioned", i.e., is equivalent to (SET LASTWORD FORM) (see page 20.18). For example, immediately after examining the value of LONGVARIABLENAME, the user could set it by typing \$\(\infty\) followed by a form.

Note that an atom of the form  $X \leftarrow Y$ , appearing at the top level of a **PROG**, will *not* be recognized as an assignment statement because it will be interpreted as a **PROG** label by the Interlisp interpreter, and therefore will not cause an error, so DWIM and CLISP will never get to see it. Instead, one must write  $(X \leftarrow Y)$ .

[CLISP Operator]

> [CLISP Operator]

Angle brackets are used in CLISP to indicate list construction. The appearance of a "<" corresponds to a "(" and indicates that a list is to be constructed containing all the elements up to the corresponding ">". For example, <A B <C>> translates to (LIST A B (LIST C)). ! can be used to indicate that the next expression is to be inserted in the list as a segment, e.g., <A B! C> translates to (CONS A (CONS B C)) and <! A ! B C> to (APPEND A B (LIST C)). !! is used to indicate that the next expression is to be inserted as a segment, and furthermore, all list

21.10

structure to its right in the angle brackets is to be physically attached to it, e.g., <!! A B> translates to (NCONC1 A B), and <!!A !B !C> to (NCONC A (APPEND B C)). Not (NCONC (APPEND A B) C), which would have the same value, but would attach C to B, and not attach either to A. Note that <,!,!!, and > need not be separate atoms, for example, <A B! C> may be written equally well as < A B!C >. Also, arbitrary Interlisp or CLISP forms may be used within angle brackets. For example, one can write <FOO (FIE X)! Y> which translates to (CONS (SETQ FOO (FIE X)) Y). CLISPIFY converts expressions in CONS, LIST, APPEND, NCONC, NCONC1, /NCONC, and /NCONC1 into equivalent CLISP expressions using <, >,!, and !!.

Note: brackets differ from other CLISP operators. For example, <A B 'C> translates to (LIST A B (QUOTE C)) even though following ', all operators are ignored for the rest of the identifier. (This is true only if a previous unmatched < has been seen, e.g., (PRINT 'A>B) will print the atom A>B.) Note however that <A B 'C> D> is equivalent to (LIST A B (QUOTE C>) D).

#### [CLISP Operator]

CLISP recognizes 'as a prefix operator. 'means QUOTE when it is the first character in an identifier, and is ignored when it is used in the interior of an identifier. Thus, X = 'Y means (EQ X (QUOTE Y)), but X = CAN'T means (EQ X CAN'T), not (EQ X CAN) followed by (QUOTE T). This enables users to have variable and function names with 'in them (so long as the 'is not the first character).

Following ', all operators are ignored for the rest of the identifier, e.g., '\*A means (QUOTE \*A), and 'X = Y means (QUOTE X = Y), not (EQ (QUOTE X) Y). To write (EQ (QUOTE X) Y), one writes Y = 'X, or 'X = Y. This is one place where an extra space does make a difference.

On typein, '\$ (escape) is equivalent to (QUOTE VALUE-OF-LASTWORD) (see page 20.18). For example, after calling PRETTYPRINT on LONGFUNCTION, the user could move its definition to FOO by typing (MOVD '\$ 'FOO).

Note that this is not (MOVD \$ 'FOO), which would be equivalent to (MOVD LONGFUNCTION 'FOO), and would (probably) cause a U.B.A. LONGFUNCTION error, nor MOVD(\$ FOO), which would actually move the definition of \$ to FOO, since DWIM and the spelling corrector would never be invoked.

#### [CLISP Operator]

CLISP recognizes ~ as a prefix operator meaning NOT. ~ can negate a form, as in ~(ASSOC X Y), or ~X, or negate an infix operator, e.g., (A ~GT B) is the same as (A LEQ B). Note that ~A = B means (EQ (NOT A) B).

When  $\tilde{}$  negates an operator, e.g.,  $\tilde{}$  = ,  $\tilde{}$  LT, the two operators are treated as a single operator whose precedence is that of the second operator. When "negates a function, e.g., ("FOO X Y), it negates the whole form, i.e., (~(FOO X Y)).

Order of Prededence of CLISP Operators:

← (left precedence)

- (unary), ~

Î \*,/

+, - (binary)

← (right precedence)

Interlisp forms

LT, GT, EQUAL, MEMBER, etc.

AND

OR

IF, THEN, ELSEIF, ELSE

iterative statement operators

#### 21.3 **Declarations**

CLISP declarations are used to affect the choice of Interlisp function used as the translation of a particular operator. For example, A + B can be translated as either (PLUS A B), (FPLUS A B), or (IPLUS A B), depending on the declaration in effect. Similarly X:1←Y can mean (RPLACA X Y), (FRPLACA X Y), or (/RPLACA X Y), and <!! A B> either (NCONC1 A B) or (/NCONC1 Note that the choice of function on all CLISP A B). transformations are affected by the CLISP declaration in effect, i.e., iterative statements, pattern matches, record operations, as well as infix and prefix operators.

#### (CLISPDEC DECLST)

[Function]

Puts into effect the declarations in DECLST. CLISPDEC performs spelling corrections on words not recognized as declarations. CLISPDEC is undoable.

The user can makes (changes) a global declaration by calling CLISPDEC with DECLST a list of declarations, e.g., (CLISPDEC '(FLOATING UNDOABLE)). Changing a global declaration does not affect the speed of subsequent CLISP transformations, since all CLISP transformation are table driven (i.e., property list), and global declarations are accomplished by making the appropriate internal changes to CLISP at the time of the declaration. If a function employs *local* declarations (described below), there will be a slight loss in efficiency owing to the fact that for each CLISP transformation, the declaration list must be searched for possibly relevant declarations.

Declarations are implemented in the order that they are given, so that later declarations override earlier ones. For example, the declaration FAST specifies that FRPLACA, FRPLACD, FMEMB, and FLAST be used in place of RPLACA, RPLACD, MEMB, and LAST; the declaration RPLACA specifies that RPLACA be used. Therefore, the declarations (FAST RPLACA RPLACD) will cause FMEMB, FLAST, RPLACA, and RPLACD to be used.

The initial global declaration is MIXED and STANDARD.

The table below gives the declarations available in CLISP, and the Interlisp functions they indicate:

Declaration:

Interlisp Functions to be used:

**MIXED** 

PLUS, MINUS, DIFFERENCE, TIMES, QUOTIENT, LESSP, GREATERP

**INTEGER or FIXED** 

IPLUS, IMINUS, IDIFFERENCE, ITIMES, IQUOTIENT, ILESSP,

**IGREATERP** 

**FLOATING** 

FPLUS, FMINUS, FDIFFERENCE, FTIMES, FQUOTIENT, LESSP,

corresponding function

The user can also make local declarations affecting a selected function or functions by inserting an expression of the form (CLISP: . DECLARATIONS) immediately following the argument list, i.e., as CADDR of the definition. Such local declarations take precedence over global declarations. Declarations affecting selected variables can be indicated by lists, where the first element is the name of a variable, and the rest of the list the declarations for that variable. For example, (CLISP: FLOATING (X INTEGER)) specifies that in this function integer arithmetic be used for computations involving X, and floating arithmetic for all other computations, where "involving" means where the variable itself is an operand. For example, with the declaration (FLOATING (X INTEGER)) in effect, (FOO X) + (FIE X) would translate to FPLUS, i.e., use floating arithmetic, even though X appears somewhere inside of the operands, whereas X + (FIE X)

would translate to IPLUS. If there are declarations involving both operands, e.g., X + Y, with (X FLOATING) (Y INTEGER), whichever appears first in the declaration list will be used.

The user can also make local record declarations by inserting a record declaration, e.g., (RECORD --), (ARRAYRECORD --), etc., in the local declaration list. In addition, a local declaration of the form (RECORDS A B C) is equivalent to having copies of the global declarations A, B, and C in the local declaration. Local record declarations override global record declarations for the function in which they appear. Local declarations can also be used to override the global setting of certain DWIM/CLISP parameters effective only for transformations within that function, by including in the local declaration an expression of the form (VARIABLE = VALUE), e.g., (PATVARDEFAULT = QUOTE).

The CLISP: expression is converted to a comment of a special form recognized by CLISP. Whenever a CLISP transformation that is affected by declarations is about to be performed in a function, this comment will be searched for a relevant declaration, and if one is found, the corresponding function will be used. Otherwise, if none are found, the global declaration(s) currently in effect will be used.

Local declarations are effective in the order that they are given, so that later declarations can be used to override earlier ones, e.g., (CLISP: FAST RPLACA RPLACD) specifies that FMEMB, FLAST, RPLACA, and RPLACD be used. An exception to this is that declarations for specific variables take precedence of general, function-wide declarations, regardless of the order of appearance, as in (CLISP: (X INTEGER) FLOATING).

CLISPIFY also checks the declarations in effect before selecting an infix operator to ensure that the corresponding CLISP construct would in fact translate back to this form. For example, if a FLOATING declaration is in effect, CLISPIFY will convert (FPLUS X Y) to X + Y, but leave (IPLUS X Y) as is. Note that if (FPLUS X Y) is CLISPIFYed while a FLOATING declaration is under effect, and then the declaration is changed to INTEGER, when X + Y is translated back to Interlisp, it will become (IPLUS X Y).

## 21.4 CLISP Operation

CLISP is a part of the basic Interlisp system. Without any special preparations, the user can include CLISP constructs in programs, or type them in directly for evaluation (in EVAL or APPLY format), then, when the "error" occurrs, and DWIM is called, it will destructively transform the CLISP to the equivalent Interlisp

21.14

expression and evaluate the Interlisp expression. CLISP transformations, like all DWIM corrections, are undoable. User approval is not requested, and no message is printed. Note that this entire discussion also applies to CLISP transformation initiated by calls to DWIM from **DWIMIFY**.

However, if a CLISP construct contains an error, an appropriate diagnostic is generated, and the form is left unchanged. For example, if the user writes (LIST X + Y\*), the error diagnostic MISSING OPERAND AT X + Y\* IN (LIST X + Y\*) would be generated. Similarly, if the user writes (LAST + EL X), CLISP knows that ((IPLUS LAST EL) X) is not a valid Interlisp expression, so the error diagnostic MISSING OPERATOR IN (LAST + EL X) is generated. (For example, the user might have meant to say (LAST + EL\*X).) Note that if LAST + EL were the name of a defined function, CLISP would never see this form.

Since the bad CLISP transformation might not be CLISP at all, for example, it might be a misspelling of a user function or variable, DWIM-holds all CLISP error messages until after trying other corrections. If one of these succeeds, the CLISP message is discarded. Otherwise, if all fail, the message is printed (but no change is made). For example, suppose the user types (R/PLACA X Y). CLISP generates a diagnostic, since ((IQUOTIENT R PLACA) X Y) is obviously not right. However, since R/PLACA spelling corrects to /RPLACA, this diagnostic is never printed.

Note: CLISP error messages are not printed on type-in. For example, typing X + \*Y will just produce a U.B.A. X + \*Y message.

If a CLISP infix construct is well formed from a syntactic standpoint, but one or both of its operands are atomic and not bound, it is possible that either the operand is misspelled, e.g., the user wrote X + YY for X + Y, or that a CLISP transformation operation was not intended at all, but that the entire expression is a misspelling. For the purpose of DWIMIFYing, "not bound" means no top level value, not on list of bound variables built up by DWIMIFY during its analysis of the expression, and not on NOFIXVARSLST, i.e., not previously seen.

For example, if the user has a variable named LAST-EL, and writes (LIST LAST-ELL). Therefore, CLISP computes, but does not actually perform, the indicated infix transformation. DWIM then continues, and if it is able to make another correction, does so, and ignores the CLISP interpretation. For example, with LAST-ELL, the transformation LAST-ELL -> LAST-EL would be found.

If no other transformation is found, and DWIM is about to interpret a construct as CLISP for which one of the operands is not bound, DWIM will ask the user whether CLISP was intended, in this case by printing LAST-ELL TREAT AS CLISP?

CLISP

Note: If more than one infix operator was involved in the CLISP construct, e.g., X + Y + Z, or the operation was an assignment to a variable already noticed, or TREATASCLISPFLG is T (initially NIL), the user will simply be informed of the correction, e.g., X + Y + Z TREATED AS CLISP. Otherwise, even if DWIM was enabled in TRUSTING mode, the user will be asked to approve the correction.

The same sort of procedure is followed with 8 and 9 errors. For example, suppose the user writes FOO8\*X where FOO8 is not bound. The CLISP transformation is noted, and DWIM proceeds. It next asks the user to approve FOO8\*X -> FOO ( \*X. For example, this would make sense if the user has (or plans to define) a function named \*X. If he refuses, the user is asked whether FOO8\*X is to be treated as CLISP. Similarly, if FOO8 were the name of a variable, and the user writes FOOO8\*X, he will first be asked to approve FOOO8\*X -> FOOO ( XX, and if he refuses, then be offered the FOOO8 -> FOO8 correction. The 8-9 transformation is tried before spelling correction since it is empirically more likely that an unbound atom or undefined function containing an 8 or a 9 is a parenthesis error, rather than a spelling error.

CLISP also contains provision for correcting misspellings of infix operators (other than single characters), IF words, and i.s. operators. This is implemented in such a way that the user who does not misspell them is not penalized. For example, if the user writes IF N = 0 THEN 1 ELSSE N\*(FACT N-1) CLISP does not operate by checking each word to see if it is a misspelling of IF, THEN, ELSE, or ELSEIF, since this would seriously degrade CLISP's performance on all IF statements. Instead, CLISP assumes that all of the IF words are spelled correctly, and transforms the expression to (COND ((ZEROP N) 1 ELSSE N\*(FACT N-1))). Later, after DWIM cannot find any other interpretation for ELSSE, and using the fact that this atom originally appeared in an IF statement, DWIM attempts spelling correction, using (IF THEN ELSE ELSEIF) for a spelling list. When this is successful, DWIM "fails" all the way back to the original IF statement, changes ELSSE to ELSE, and starts over. Misspellings of AND, OR, LT, GT, etc. are handled similarly.

CLISP also contains many Do-What-I-Mean features besides spelling corrections. For example, the form (LIST + X Y) would generate a MISSING OPERATOR error. However, (LIST -X Y) makes sense, if the minus is unary, so DWIM offers this interpretation to the user. Another common error, especially for new users, is to write (LIST X\*FOO(Y)) or (LIST X\*FOO Y), where FOO is the name of a function, instead of (LIST X\*(FOO Y)). Therefore, whenever an operand that is not bound is also the name of a function (or corrects to one), the above interpretations are offered.

### 21.5 CLISP Translations

The translation of CLISP character operators and the CLISP word IF are handled by *replacing* the CLISP expression with the corresponding Interlisp expression, and discarding the original CLISP. This is done because (1) the CLISP expression is easily recomputable (by CLISPIFY) and (2) the Interlisp expressions are simple and straightforward. Another reason for discarding the original CLISP is that it may contain errors that were corrected in the course of translation (e.g., FOO←FOOO:1, N\*8FOO X), etc.). If the original CLISP were retained, either the user would have to go back and fix these errors by hand, thereby negating the advantage of having DWIM perform these corrections, or else DWIM would have to keep correcting these errors over and over.

Note that CLISPIFY is sufficiently fast that it is practical for the user to configure his Interlisp system so that all expressions are automatically CLISPIFYed immediately before they are presented to him. For example, he can define an edit macro to use in place of P which calls CLISPIFY on the current expression before printing it. Similarly, he can inform PRETTYPRINT to call CLISPIFY on each expression before printing it, etc.

Where (1) or (2) are not the case, e.g., with iterative statements, pattern matches, record expressions, etc. the original CLISP is retained (or a slightly modified version thereof), and the translation is stored elsewhere (by the function CLISPTRAN, page 21.25), usually in the hash array CLISPARRAY. The interpreter automatically checks this array when given a form CAR of which is not a function. Similarly, the compiler performs a GETHASH when given a form it does not recognize to see if it has a translation, which is then compiled instead of the form. Whenever the user changes a CLISP expresson by editing it, the editor automatically deletes its translation (if one exists), so that the next time it is evaluated or dwimified, the expression will be retranslated (if the value of CLISPRETRANFLG is T, DWIMIFY will also (re)translate any expressions which have translations stored remotely, see page 21.22). The function PPT and the edit commands PPT and CLISP: are available for examining translations (page 21.26).

The user can also indicate that he wants the original CLISP retained by embedding it in an expression of the form (CLISP. CLISP-EXPRESSION), e.g., (CLISP X:5:3) or (CLISP < A B C!D>). In such cases, the translation will be stored remotely as described above. Furthermore, such expressions will be treated as CLISP even if infix and prefix transformations have been disabled by setting CLISPFLG to NIL (page 21.25). In other words, the user can instruct the system to interpret as CLISP infix or prefix constructs only those expressions that are specifically flagged as such. The user can also include CLISP declarations by writing

(CLISP DECLARATIONS . FORM), e.g., (CLISP (CLISP: FLOATING) ...
). These declarations will be used in place of any CLISP declarations in the function definition. This feature provides a way of including CLISP declarations in macro definitions.

Note: CLISP translations can also be used to supply an interpretation for function objects, as well as forms, either for function objects that are used openly, i.e., appearing as CAR of form, function objects that are explicitly APPLYed, as with arguments to mapping functions, or function objects contained in function definition cells. In all cases, if CAR of the object is not LAMBDA or NLAMBDA, the interpreter and compiler will check CLISPARRAY.

#### 21.6 DWIMIFY

**DWIMIFY** is effectively a preprocessor for CLISP. **DWIMIFY** operates by scanning an expression as though it were being interpreted, and for each form that would generate an error, calling DWIM to "fix" it. **DWIMIFY** performs all DWIM transformations, not just CLISP transformations, so it does spelling correction, fixes 8-9 errors, handles F/L, etc. Thus the user will see the same messages, and be asked for approval in the same situations, as he would if the expression were actually run. If DWIM is unable to make a correction, no message is printed, the form is left as it was, and the analysis proceeds.

**DWIMIFY** knows exactly how the interpreter works. It knows the syntax of PROGs, SELECTQs, LAMBDA expressions, SETQs, et al. It knows how variables are bound, and that the argument of NLAMBDAs are not evaluated (the user can inform DWIMIFY of a function or macro's nonstandard binding or evaluation by giving it a suitable INFO property, see page 21.21). In the course of its analysis of a particular expression, DWIMIFY builds a list of the bound variables from the LAMBDA expressions and PROGs that it encounters. It uses this list for spelling corrections. DWIMIFY also knows not to try to "correct" variables that are on this list since they would be bound if the expression were actually being run. However, note that DWIMIFY cannot, a priori, know about variables that are used freely but would be bound in a higher function if the expression were evaluated in its normal context. Therefore, DWIMIFY will try to "correct" these variables. Similarly, DWIMIFY will attempt to correct forms for which CAR is undefined, even when the form is not in error from the user's standpoint, but the corresponding function has simply not yet been defined.

21.18 CLISP

Note: **DWIMIFY** rebinds **FIXSPELLDEFAULT** to **N**, so that if the user is not at the terminal when dwimifying (or compiling), spelling corrections will not be performed.

**DWIMIFY** will also inform the user when it encounters an expression with too *many* arguments (unless **DWIMCHECK#ARGSFLG = NIL**), because such an occurrence, although does not cause an error in the Interlisp interpreter, nevertheless is frequently symptomatic of a parenthesis error. For example, if the user wrote (CONS (QUOTE FOO X)) instead of (CONS (QUOTE FOO) X), DWIMIFY will print:

POSSIBLE PARENTHESIS ERROR IN (QUOTE FOO X)
TOO MANY ARGUMENTS (MORE THAN 1)

**DWIMIFY** will also check to see if a **PROG** label contains a clisp character (unless **DWIMCHECKPROGLABELSFLG = NIL**, or the label is a member of **NOFIXVARSLST**), and if so, will alert the user by printing the message **SUSPICIOUS PROG LABEL**, followed by the label. The **PROG** label will *not* be treated as CLISP.

Note that in most cases, an attempt to transform a form that is already as the user intended will have no effect (because there will be nothing to which that form could reasonably be transformed). However, in order to avoid needless calls to DWIM or to avoid possible confusion, the user can inform DWIMIFY not to attempt corrections or transformations on certain functions or variables by adding them to the list NOFIXFNSLST or NOFIXVARSLST respectively. Note that the user could achieve the same effect by simply setting the corresponding variables, and giving the functions dummy definitions.

**DWIMIFY** will never attempt corrections on global variables, i.e., variables that are a member of the list **GLOBALVARS**, or have the property **GLOBALVAR** with value **T**, on their property list. Similarly, **DWIMIFY** will not attempt to correct variables declared to be **SPECVARS** in block declarations or via **DECLARE** expressions in the function body. The user can also declare variables that are simply used freely in a function by using the **USEDFREE** declaration.

DWIMIFY and DWIMIFYFNS (used to DWIMIFY several functions) maintain two internal lists of those functions and variables for which corrections were unsuccessfully attempted. These lists are initialized to the values of NOFIXFNSLST and NOFIXVARSLST. Once an attempt is made to fix a particular function or variable, and the attempt fails, the function or variable is added to the corresponding list, so that on subsequent occurrences (within this call to DWIMIFY or DWIMIFYFNS), no attempt at correction is made. For example, if FOO calls FIE several times, and FIE is undefined at the time FOO is dwimified, DWIMIFY will not bother with FIE after the first occurrence. In other words, once

CLISP

**DWIMIFY** "notices" a function or variable, it no longer attempts to correct it. **DWIMIFY** and **DWIMIFYFNS** also "notice" free variables that are set in the expression being processed. Moreover, once **DWIMIFY** "notices" such functions or variables, it subsequently treats them the same as though they were actually defined or set.

Note that these internal lists are local to each call to DWIMIFY and DWIMIFYFNS, so that if a function containing FOOO, a misspelled call to FOO, is DWIMIFYed before FOO is defined or mentioned, if the function is DWIMIFYed again after FOO has been defined, the correction will be made.

The user can undo selected transformations performed by **DWIMIFY**, as described on page 13.14.

#### (DWIMIFY X QUIETFLG L)

[Function]

Performs all DWIM and CLISP corrections and transformations on X that would be performed if X were run, and prints the result unless QUIETFLG = T.

If X is an atom and L is **NIL**, X is treated as the name of a function, and its entire definition is dwimified. If X is a list or L is not **NIL**, X is the expression to be dwimified. If L is not **NIL**, it is the edit push-down list leading to X, and is used for determining context, i.e., what bound variables would be in effect when X was evaluated, whether X is a form or sequence of forms, e.g., a **COND** clause, etc.

If X is an iterative statement and L is NIL, DWIMIFY will also print the translation, i.e., what is stored in the hash array.

#### (DWIMIFYFNS FN<sub>1</sub> ... FN<sub>N</sub>)

[NLambda NoSpread Function]

Dwimifies each of the functions given. If only one argument is given, it is evalued. If its value is a list, the functions on this list are dwimified. If only one argument is given, it is atomic, its value is not a list, and it is the name of a known file, DWIMIFYFNS will operate on (FILEFNSLST FN<sub>1</sub>), e.g. (DWIMIFYFNS FOO.LSP) will dwimify every function in the file FOO.LSP.

Every 30 seconds, **DWIMIFYFNS** prints the name of the function it is processing, a la **PRETTYPRINT**.

Value is a list of the functions dwimified.

#### **DWIMINMACROSFLG**

[Variable]

Controls how **DWIMIFY** treats the arguments in a "call" to a macro, i.e., where the **CAR** of the form is undefined, but has a macro definition. If **DWIMINMACROSFLG** is T, then macros are treated as **LAMBDA** functions, i.e., the arguments are assumed to

21.20

	be evaluated, which means that <b>DWIMIFY</b> will descend into the argument list. If <b>DWIMINMACROSFLG</b> is <b>NIL</b> , macros are treated as <b>NLAMBDA</b> functions. <b>DWIMINMACROSFLG</b> is initially <b>T</b> .	
INFO	[Property Name]	
	Used to inform <b>DWIMIFY</b> of nonstandard behavior of particular forms with respect to evaluation, binding of arguments, etc. The <b>INFO</b> property of a litatom is a single atom or list of atoms chosen from among the following:	
EVAL	Informs <b>DWIMIFY</b> (and CLISP and Masterscope) that an nlambda function <i>does</i> evaluate its arguments. Can also be placed on a macro name to override the behavior of <b>DWIMINMACROSFLG</b> = <b>NIL</b> .	
NOEVAL	Informs <b>DWIMIFY</b> that a macro does <i>not</i> evaluate all of its arguments, even when <b>DWIMINMACROSFLG</b> = $T$ .	
BINDS	Placed on the INFO property of a function or the CAR of a special form to inform DWIMIFY that the function or form binds variables. In this case, DWIMIFY assumes that CADR of the form is the variable list, i.e., a list of litatoms, or lists of the form (VAL VALUE). LAMBDA, NLAMBDA, PROG, and RESETVARS are handled in this fashion.	
LABELS	Informs <b>CLISPIFY</b> that the form interprets top-level litatoms as labels, so that <b>CLISPIFY</b> will never introduce an atom (by packing) at the top level of the expression. <b>PROG</b> is handled in this fashion.	
NOFIXFNSLST	[Variable]	
	List of functions that DWIMIFY will not try to correct.	
NOFIXVARSLST	[Variable]	
	List of variables that <b>DWIMIFY</b> will not try to correct.	
NOSPELLFLG	[Variable]	
	If <b>T</b> , <b>DWIMIFY</b> will not perform any spelling corrections. Initially <b>NIL</b> . <b>NOSPELLFLG</b> is reset to <b>T</b> when compiling functions whose definitions are obtained from a file, as opposed to being in core.	
CLISPHELPFLG	[Variable]  If NIL, DWIMIFY will not ask the user for approval of any CLISP transformations. Instead, in those situations where approval would be required, the effect is the same as though the user had been asked and said NO. Initially T.	

DWIMIFYCOMPFLG		[Variable]
	If <b>T</b> , <b>DWIMIFY</b> is called before compiling an expression <b>NIL</b> .	on. Initially
DWIMCHECK#ARGSFLG		[Variable]
	If T, causes DWIMIFY to check for too many argument Initially T.	ts in a form.
DWIMCHECKPROGLABELS	SFLG	[Variable]
	If T, causes DWIMIFY to check whether a PROG labe CLISP character. Initially T.	l contains a
DWIMESSGAG		[Variable]
	If T, suppresses all DWIMIFY error messages. Initially NIL.	
CLISPRETRANFLG		[Variable]
	If T, informs DWIMIFY to (re)translate all expressions remote translations in the CLISP hash array. Initially N	

#### 21.7 CLISPIFY

CLISPIFY converts Interlisp expressions to CLISP. Note that the expression given to CLISPIFY need not have originally been input as CLISP, i.e., CLISPIFY can be used on functions that were written before CLISP was even implemented. CLISPIFY is cognizant of declaration rules as well as all of the precedence rules. For example, CLISPIFY will convert (IPLUS A (ITIMES B C)) into A+B\*C, but (ITIMES A (IPLUS B C)) into A\*(B+C). CLISPIFY handles such cases by first DWIMIFYing the expression. CLISPIFY also knows how to handle expressions consisting of a mixture of Interlisp and CLISP, e.g., (IPLUS A B\*C) is converted to A + B\*C, but (ITIMES A B + C) to (A\*(B+C)). CLISPIFY converts calls to the six basic mapping functions, MAP, MAPC, MAPCAR, MAPLIST, MAPCONC, and MAPCON, into equivalent iterative statements. It also converts certain easily recognizable internal PROG loops to the corresponding iterative statements. CLISPIFY can convert all iterative statements input in CLISP back to CLISP, regardless of how complicated the translation was, because the original CLISP is saved.

**CLISPIFY** is not destructive to the original Interlisp expression, i.e., **CLISPIFY** produces a new expression without changing the original. The new expression may however contain some "pieces" of the original, since **CLISPIFY** attempts to minimize the number of **CONS**es by not copying structure whenever possible.

CLISPIFY will not convert expressions appearing as arguments to NLAMBDA functions, except for those functions whose INFO property is or contains the atom EVAL. CLISPIFY also contains built in information enabling it to process special forms such as PROG, SELECTQ, etc. If the INFO property is or contains the atom LABELS, CLISPIFY will never create an atom (by packing) at the top level of the expression. PROG is handled in this fashion.

Note: Disabling a CLISP operator with CLDISABLE (page 21.26) will also disable the corresponding CLISPIFY transformation. Thus, if  $\leftarrow$  is "turned off",  $A \leftarrow B$  will not transform to (SETQ A B), nor vice versa.

#### (CLISPIFY X EDITCHAIN)

[Function]

Clispifies X. If X is an atom and EDITCHAIN is NIL, X is treated as the name of a function, and its definition (or EXPR property) is clispified. After CLISPIFY has finished, X is redefined (using /PUTD) with its new CLISP definition. The value of CLISPIFY is X. If X is atomic and not the name of a function, spelling correction is attempted. If this fails, an error is generated.

If X is a list, or EDITCHAIN is not NIL, X itself is the expression to be clispified. If EDITCHAIN is not NIL, it is the edit push-down list leading to X and is used to determine context as with DWIMIFY, as well as to obtain the local declarations, if any. The value of CLISPIFY is the clispified version of X.

#### (CLISPIFYFNS FN1 ... FNN)

[NLambda NoSpread Function]

Like **DWIMIFYFNS** (page 21.20) except calls **CLISPIFY** instead of **DWIMIFY**.

#### CL:FLG

[Variable]

Affects CLISPIFY's handling of forms beginning with CAR, CDR, ... CDDDDR, as well as pattern match and record expressions. If CL:FLG is NIL, these are not transformed into the equivalent: expressions. This will prevent CLISPIFY from constructing any expression employing a: infix operator, e.g., (CADR X) will not be transformed to X:2. If CL:FLG is T, CLISPIFY will convert to: notation only when the argument is atomic or a simple list (a function name and one atomic argument). If CL:FLG is ALL, CLISPIFY will convert to: expressions whenever possible.

CL:FLG is initially T.

#### **CLREMPARSFLG**

[Variable]

If T, CLISPIFY will remove parentheses in certain cases from simple forms, where "simple" means a function name and one or two atomic arguments. For example, (COND ((ATOM X) --)) will CLISPIFY to (IF ATOM X THEN --). However, if CLREMPARSFLG is

CLISP

set to NIL, CLISPIFY will produce (IF (ATOM X) THEN --). Note that regardless of the setting of this flag, the expression can be input in either form.

**CLREMPARSFLG** is initially **NIL**.

#### **CLISPIFYPACKFLG**

[Variable]

**CLISPIFYPACKFLG** affects the treatment of infix operators with atomic operands. If **CLISPIFYPACKFLG** is **T**, **CLISPIFY** will pack these into single atoms, e.g., (IPLUS A (ITIMES B C)) becomes A + B\*C. If **CLISPIFYPACKFLG** is **NIL**, no packing is done, e.g., the above becomes A + B \* C.

**CLISPIFYPACKFLG** is initially T.

#### **CLISPIFYUSERFN**

[Variable]

If T, causes the function CLISPIFYUSERFN, which should be a function of one argument, to be called on each form (list) not otherwise recognized by CLISPIFY. If a non-NIL value is returned, it is treated as the clispified form. Initially NIL

Note that CLISPIFYUSERFN must be both set and defined to use this feature.

#### **FUNNYATOMLST**

[Variable]

Suppose the user has variables named A, B, and A\*B. If CLISPIFY were to convert (ITIMES A B) to A\*B, A\*B would not translate back correctly to (ITIMES A B), since it would be the name of a variable, and therefore would not cause an error. The user can prevent this from happening by adding A\*B to the list FUNNYATOMLST. Then, (ITIMES A B) would CLISPIFY to A \* B.

Note that A\*B's appearance on FUNNYATOMLST would not enable DWIM and CLISP to decode A\*B+C as (IPLUS A\*B C); FUNNYATOMLST is used only by CLISPIFY. Thus, if an identifier contains a CLISP character, it should always be separated (with spaces) from other operators. For example, if X\* is a variable, the user should write (SETQ X\* FORM) in CLISP as X\*  $\leftarrow$ FORM, not X\*  $\leftarrow$ FORM. In general, it is best to avoid use of identifiers containing CLISP character operators as much as possible.

## 21.8 Miscellaneous Functions and Variables

CLISPFLG	[Variable]
	If <b>CLISPFLG = NIL</b> , disables all CLISP infix or prefix transformations (but does not affect <b>IF/THEN/ELSE</b> statements, or iterative statements).
	If <b>CLISPFLG = TYPE-IN</b> , CLISP transformations are performed only <b>on expressions</b> that are typed in for evaluation, i.e., not on user programs.
	If <b>CLISPFLG</b> = <b>T</b> , CLISP transformations are performed on all expressions.
	The initial value for <b>CLISPFLG</b> is <b>T</b> . <b>CLISPIFY</b> ing anything will cause <b>CLISPFLG</b> to be set to <b>T</b> .
CLISPCHARS	[Variable]
	A list of the operators that can appear in the interior of an atom. Currently $(+ - */ \uparrow ~" = \leftarrow : < > + - ~= @ !)$ .
CLISPCHARRAY	[Variable]
	A bit table of the characters on CLISPCHARS used for calls to STRPOSL (page 4.6). CLISPCHARRAY is initialized by performing (SETQ CLISPCHARRAY (MAKEBITTABLE CLISPCHARS)).
CLISPINFIXSPLST	[Variable]
	A list of infix operators used for spelling correction.
CLISPARRAY	[Variable]
	Hash array used for storing CLISP translations. CLISPARRAY is checked by FAULTEVAL and FAULTAPPLY on erroneous forms before calling DWIM, and by the compiler.
(CLISPTRAN X TRAN)	[Function]
	Gives X the translation TRAN by storing (key X, value TRAN) in the hash array CLISPARRAY. CLISPTRAN is called for all CLISP translations, via a non-linked, external function call, so it can be advised.
(CLISPDEC DECLST)	[Function]
	Puts into effect the declarations in <i>DECLST</i> (see page 21.12). <b>CLISPDEC</b> performs spelling corrections on words not recognized as declarations. <b>CLISPDEC</b> is undoable.

(CLDISABLE OP)	[Function]
	Disables the CLISP operator <i>OP</i> . For example, (CLDISABLE '-) makes - be just another character. CLDISABLE can be used on all CLISP operators, e.g., infix operators, prefix operators, iterative statement operators, etc. CLDISABLE is undoable.
	Note: Simply removing a character operator from CLISPCHARS will prevent it from being treated as a CLISP operator when it appears as part of an atom, but it will continue to be an operator when it appears as a separate atom, e.g. (FOO + X) vs FOO + X.
CLISPIFTRANFLG	[Variable]
	Affects handling of translations of IF-THEN-ELSE statements (see page 9.5). If T, the translations are stored elsewhere, and the (modified) CLISP retained. If NIL, the corresponding COND expression replaces the CLISP. Initially T.
CLISPIFYPRETTYFLG	[Variable]
	If non-NIL, causes PRETTYPRINT (and therefore PP and MAKEFILE) to CLISPIFY selected function definitions before printing them according to the following interpretations of CLISPIFYPRETTYFLG:
ALL	Clispify all functions.
T or EXPRS	Clispify all functions currently defined as EXPRs.
CHANGES	Clispify all functions marked as having been changed.
a list	Clispify all functions in that list.
	CLISPIFYPRETTYFLG is (temporarily) reset to T when MAKEFILE is called with the option CLISPIFY, and reset to CHANGES when the file being dumped has the property FILETYPE value CLISP. CLISPIFYPRETTYFLG is initially NIL.
	Note: If CLISPIFYPRETTYFLG is non-NIL, and the only transformation performed by DWIM are well formed CLISP transformations, i.e., no spelling corrections, the function will not be marked as changed, since it would only have to be re-clispified and re-prettyprinted when the file was written out.
(PPT X)	[NLambda NoSpread Function]
	Both a function and an edit macro for prettyprinting translations. It performs a PP after first resetting PRETTYTRANFLG to T, thereby causing any translations to be printed instead of the corresponding CLISP.
CLISP:	[Editor Command]
	Edit macro that obtains the translation of the correct expression, if any, from CLISPARRAY, and calls EDITE on it.

CL	[Editor Command]		
	Edit macro. Replaces current expression with CLISPIFYed current		
	expression. Current expression can be an element or tail.		
DW	[Editor Command]		
	Edit macro. <b>DWIMIFY</b> s current expression, which can be an element (atom or list) or tail.		
	Both <b>CL</b> and <b>DW</b> can be called when the current expression is either an element or a tail and will work properly. Both consult the declarations in the function being edited, if any, and both are undoable.		
(LOWERCASE FLG)	[Function]		
	If FLG = T, LOWERCASE makes the necessary internal		
	modifications so that CLISPIFY will use lower case versions of		
	AND, OR, IF, THEN, ELSE, ELSEIF, and all i.s. operators. This		
	produces more readable output. Note that the user can always		
	type in either upper or lower case (or a combination), regardless		
	of the action of LOWERCASE. If FLG = NIL, CLISPIFY will use		
	uppercase versions of AND, OR, et al. The value of LOWERCASE		

setting for LOWERCASE is T.

#### 21.9 CLISP Internal Conventions

CLISP is almost entirely table driven by the property lists of the corresponding infix or prefix operators. For example, much of the information used for translating the + infix operator is stored on the property list of the litatom "+". Thus it is relatively easy to add new infix or prefix operators or change old ones, simply by adding or changing selected property values. (There is some built in information for handling minus, :, ', and ~, i.e., the user could not himself add such "special" operators, although he can disable or redefine them.)

is its previous "setting". LOWERCASE is undoable. The initial

Global declarations operate by changing the LISPFN and CLISPINFIX properties of the appropriate operators.

#### **CLISPTYPE**

#### [Property Name]

The property value of the property CLISPTYPE is the precedence number of the operator: higher values have higher precedence, i.e., are tighter. Note that the actual value is unimportant, only the value relative to other operators. For example, CLISPTYPE for:, ↑, and \* are 14, 6, and 4 respectively. Operators with the

same precedence group left to right, e.g., / also has precedence 4, so A/B\*C is (A/B)\*C.

An operator can have a different left and right precedence by making the value of CLISPTYPE be a dotted pair of two numbers, e.g., CLISPTYPE of  $\leftarrow$  is (8 · -12). In this case, CAR is the left precedence, and CDR the right, i.e., CAR is used when comparing with operators on the *left*, and CDR with operators on the *right*. For example, A\*B $\leftarrow$ C + D is parsed as A\*(B $\leftarrow$ (C + D)) because the left precedence of  $\leftarrow$  is 8, which is higher than that of \*, which is 4. The right precedence of  $\leftarrow$  is -12, which is lower than that of +, which is 2.

If the CLISPTYPE property for any operator is removed, the corresponding CLISP transformation is disabled, as well as the inverse CLISPIFY transformation.

#### **UNARYOP**

#### [Property Name]

The value of property **UNARYOP** must be **T** for unary operators or brackets. The operand is always on the right, i.e., unary operators or brackets are always prefix operators.

#### **BROADSCOPE**

#### [Property Name]

The value of property BROADSCOPE is T if the operator has lower precedence than Interlisp forms, e.g., LT, EQUAL, AND, etc. For example, (FOO X AND Y) parses as ((FOO X) AND Y). If the BROADSCOPE property were removed from the property list of AND, (FOO X AND Y) would parse as (FOO (X AND Y)).

#### LISPFN

#### [Property Name]

The value of the property LISPFN is the name of the function to which the infix operator translates. For example, the value of LISPFN for † is EXPT, for 'QUOTE, etc. If the value of the property LISPFN is NIL, the infix operator itself is also the function, e.g., AND, OR, EQUAL.

#### **SETFN**

#### [Property Name]

If FOO has a SETFN property FIE, then (FOO --) $\leftarrow$ X translates to (FIE -- X). For example, if the user makes ELT be an infix operator, e.g. #, by putting appropriate CLISPTYPE and LISPFN properties on the property list of # then he can also make # followed by  $\leftarrow$  translate to SETA, e.g., X#N $\leftarrow$ Y to (SETA·X N Y), by putting SETA on the property list of ELT under the property SETFN. Putting the list (ELT) on the property list of SETA under property SETFN will enable SETA forms to CLISPIFY back to ELT's.

#### **CLISPINFIX**

#### [Property Name]

The value of this property is the CLISP infix to be used in CLISPIFYing. This property is stored on the property list of the corresponding Interlisp function, e.g., the value of property CLISPINFIX for EXPT is \(\bullet\), for QUOTE is 'etc.

#### **CLISPWORD**

#### [Property Name]

Appears on the property list of clisp operators which can appear as CAR of a form, such as FETCH, REPLACE, IF, iterative statement operators, etc. Value of property is of the form (KEYWORD. NAME), where NAME is the lowercase version of the operator, and KEYWORD is its type, e.g. FORWORD, IFWORD, RECORDWORD, etc.

KEYWORD can also be the name of a function. When the atom appears as CAR of a form, the function is applied to the form and the result taken as the correct form. In this case, the function should either physically change the form, or call CLISPTRAN (page 21.25) to store the translation.

As an example, to make & be an infix character operator meaning **OR**, the user could do the following:

- ←(PUTPROP'&'CLISPTYPE (GETPROP'OR'CLISPTYPE))
- ←(PUTPROP '& 'LISPFN 'OR)
- ←(PUTPROP '& 'BROADSCOPE T)
- ←(PUTPROP 'OR 'CLISPINFIX '&)
- ←(SETQ CLISPCHARS (CONS '& CLISPCHARS))
- ←(SETQ CLISPCHARRAY (MAKEBITTABLE CLISPCHARS))

TOC.2 TABLE OF CONTENTS

This chapter describes a number of areas that often contribute to performance problems in Interlisp-D programs. Many performance problems can be improved by optimizing the use of storage, since allocating and reclaiming large amounts of storage is expensive. Another tactic that can sometimes yield performance improvements is to change the use of variable bindings on the stack to reduce variable lookup time. There are a number of tools that can be used to determine which parts of a computation cause performance bottlenecks.

## 22.1 Storage Allocation and Garbage Collection

As an Interlisp-D applications program runs, it creates data structures (allocated out of free storage space), manipulates them, and then discards them. If there were no way of reclaiming this space, over time the Interlisp-D memory (both the physical memory in the machine and the virtual memory stored on the disk) would fill up, and the computation would come to a halt. Actually, long before this could happen the system would probably become intolerably slow, due to "data fragmentation," which occurs when the data currently in use are spread over many virtual memory pages, so that most of the computer time must be spent swapping disk pages into physical memory. The problem of fragmentation will occur in any situation where the virtual memory is significantly larger than the real physical memory. To reduce swapping, it is desirable to keep the "working set" (the set of pages containing actively referenced data) as small as possible.

It is possible to write programs that don't generate much "garbage" data, or which recycle data, but such programs tend to be overly complicated and difficult to debug. Spending effort writing such programs defeats the whole point of using a system with automatic storage allocation. An important part of any Lisp implementation is the "garbage collector" which identifies discarded data and reclaims its space. There are several well-known approaches to garbage collection. One method is the traditional mark-and-sweep garbage collection algorithm, which identifies "garbage" data by marking all accessible data structures, and then sweeping through the data spaces to find all

unmarked objects (i.e., not referenced by any other object). Although this method is guaranteed to reclaim all garbage, it takes time proportional to the number of allocated objects, which may be very large. (Some allocated objects will have been marked during the "mark" phase, and the remainder will be collected during the "sweep" phase; so all will have to be touched in some way.) Also, the time that a mark-and-sweep garbage collection takes is independent of the amount of garbage collected; it is possible to sweep through the whole virtual memory, and only recover a small amount of garbage.

For interactive applications, it is not acceptable to have long interruptions in a computation for the purpose of garbage Interlisp-D solves this problem by using a reference-counting garbage collector. With this scheme, there is a table containing counts of how many times each object is referenced. This table is incrementally updated as pointers are created and discarded, incurring a small overhead distributed over the computation as a whole. (Note: References from the stack are not counted, but are handled separately at "sweep" time; thus the vast majority of data manipulations do not cause updates to this table.) At opportune moments, the garbage collector scans this table, and reclaims all objects that are no longer accessible (have a reference count of zero). The pause while objects are reclaimed is only the time for scanning the reference count tables (small) plus time proportional to the amount of garbage that has to be collected (typically less than a second). "Opportune" times occur when a certain number of cells have been allocated or when the system has been waiting for the user to type something for long enough. The frequency of garbage collection is controlled by the functions and variables described below. For the best system performance, it is desirable to adjust these parameters for frequent, short garbage collections, which will not interrupt interactive applications for very long, and which will have the added benefit of reducing data fragmentation, keeping the working set small.

One problem with the Interlisp-D garbage collector is that not all garbage is guaranteed to be collected. Circular data structures, which point to themselves directly or indirectly, are never reclaimed, since their reference counts are always at least one. With time, this unreclaimable garbage may increase the working set to unacceptable levels. Some users have worked with the same Interlisp-D virtual memory for a very long time, but it is a good idea to occasionally save all of your functions in files, reinitialize Interlisp-D, and rebuild your system. Many users end their working day by issuing a command to rebuild their system and then leaving the machine to perform this task in their absence. If the system seems to be spending too much time swapping (an indication of fragmented working set), this procedure is definitely recommended.

Garbage collection in Interlisp-D is controlled by the following functions and variables:

(RECLAIM) [Function] Initiates a garbage collection. Returns 0. (RECLAIMMIN N) [Function] Sets the frequency of garbage collection. Interlisp keeps track of the number of cells of any type that have been allocated; when it reaches a given number, a garbage collection occurs. If N is non-NIL, this number is set to N. Returns the current setting of the number. RECLAIMWAIT [Variable] Interlisp-D will invoke a RECLAIM if the system is idle and waiting for user input for RECLAIMWAIT seconds (currently set for 4 seconds). (GCGAG MESSAGE) [Function] Sets the behavior that occurs while a garbage collection is taking place. If MESSAGE is non-NIL, the cursor is complemented during a RECLAIM; if MESSAGE = NIL, nothing happens. The value of GCGAG is its previous setting. (GCTRP) [Function] Returns the number of cells until the next garbage collection, according to the RECLAIMMIN number. The amount of storage allocated to different data types, how much of that storage is in use, and the amount of data fragmentation can be determined using the following function: (STORAGE TYPES PAGETHRESHOLD) [Function] STORAGE prints out a summary, for each data type, of the amount of space allocated to the data type, and how much of that space is currently in use. If TYPES is non-NIL, STORAGE only lists statistics for the specified types. TYPES can be a litatom or a list of types. If PAGETHRESHOLD is non-NIL, then STORAGE only lists statistics for types that have at least PAGETHRESHOLD pages

allocated to them.

**STORAGE** prints out a table with the column headings Type, Assigned, Free Items, In use, and Total alloc. Type is the name of the data type. Assigned is how much of your virtual memory is set aside for items of this type. Currently, memory is allocated in quanta of two pages (1024 bytes). The numbers under Assigned show the number of pages and the total number of items that fit

on those pages. Free Items shows how many items are available to be allocated (using the create construct, page 8.3); these constitute the "free list" for that data type. In use shows how many items of this type are currently in use, i.e., have pointers to them and hence have not been garbage collected. If this number is higher than your program seems to warrant, you may want to look for storage leaks. The sum of Free Items and In use is always the same as the total Assigned items. Total alloc is the total number of items of this type that have ever been allocated (see BOXCOUNT, page 22.8).

Note: The information about the number of items of type LISTP is only approximate, because list cells are allocated in a special way that precludes easy computation of the number of items per page.

Note: When a data type is redeclared, the data type name is reassigned. Pages which were assigned to instances of the old data type are labeled \*\*DEALLOC\*\*.

At the end of the table printout, STORAGE prints a "Data Spaces Summary" listing the number of pages allocated to the major data areas in the virtual address space: the space for fixed-length items (including datatypes), the space for variable-length items, and the space for litatoms. Variable-length data types such as arrays have fixed-length "headers," which is why they also appear in the printout of fixed-length data types. Thus, the line printed for the BITMAP data type says how many bitmaps have been allocated, but the "assigned pages" column counts only the headers, not the space used by the variable-length part of the bitmap. This summary also lists "Remaining Pages" in relation to the largest possible virtual memory, not the size of the virtual memory backing file in use. This file may fill up, causing a STORAGE FULL error, long before the "Remaining Pages" numbers reach zero.

STORAGE also prints out information about the sizes of the entries on the variable-length data free list. The block sizes are broken down by the value of the variable STORAGE.ARRAYSIZES, initially (4 16 64 256 1024 4096 16384 NIL), which yields a printout of the form:

#### variable-datum free list:

le 4 26 items; 104 cells. le 16 72 items; 783 cells. le 64 36 items; 964 cells. le 256 28 items; 3155 cells. le 1024 3 items; 1175 cells. le 4096 5 items; 8303 cells. le 16384 3 items; 17067 cells. others 1 items; 17559 cells. This information can be useful in determining if the variable-length data space is fragmented. If most of the free space is composed of small items, then the allocator may not be able to find room for large items, and will extend the variable datum space. If this is extended too much, this could cause an ARRAYS FULL error, even if there is a lot of space left in little chunks.

#### (STORAGE.LEFT)

[Function]

Provides a programmatic way of determining how much storage is left in the major data areas in the virtual address space. Returns a list of the form (MDSFREE MDSFRAC 8MBFRAC ATOMFREE ATOMFRAC), where the elements are interpreted as follows:

#### **MDSFREE**

The number of free pages left in the main data space (which includes both fixed-length and variable-length data types).

#### **MDSFRAC**

The fraction of the total possible main data space that is free.

#### 8MBFRAC

The fraction of the total main data space that is free, relative to eight megabytes.

This number is useful when using Interlisp-D on some early computers where the hardware limits the address space to eight megabytes. The function **32MBADDRESSABLE** returns non-**NIL** if the currently running Interlisp-D system can use the full 32 megabyte address space.

#### **ATOMFREE**

The number of free pages left in the litatom space.

#### **ATOMFRAC**

The fraction of the total litatom space that is free.

Note: Another important space resource is the amount of the virtual memory backing file in use (see VMEMSIZE, page 12.11). The system will crash if the virtual memory file is full, even if the address space is not exhausted.

## 22.2 Variable Bindings

Different implementations of lisp use different methods of accessing free variables. The binding of variables occurs when a function or a PROG is entered. For example, if the function FOO has the definition (LAMBDA (A B) BODY), the variables A and B are bound so that any reference to A or B from BODY or any function called from BODY will refer to the arguments to the function FOO and not to the value of A or B from a higher level function. All variable names (litatoms) have a top level value cell which is used if the variable has not been bound in any function. In discussions of variable access, it is useful to distinguish

between three types of variable access: local, special and global. Local variable access is the use of a variable that is bound within the function from which it is used. Special variable access is the use of a variable that is bound by another function. Global variable access is the use of a variable that has not been bound in any function. We will often refer to a variable all of whose accesses are local as a "local variable." Similarly, a variable all of whose accesses are global we call a "global variable."

In a "deep" bound system, a variable is bound by saving on the stack the variable's name together with a value cell which contains that variable's new value. When a variable is accessed, its value is found by searching the stack for the most recent binding (occurrence) and retrieving the value stored there. If the variable is not found on the stack, the variable's top level value cell is used.

In a "shallow" bound system, a variable is bound by saving on the stack the variable name and the variable's old value and putting the new value in the variable's top level value cell. When a variable is accessed, its value is always found in its top level value cell.

The deep binding scheme has one disadvantage: the amount of cpu time required to fetch the value of a variable depends on the stack distance between its use and its binding. The compiler can determine local variable accesses and compiles them as fetches directly from the stack. Thus this computation cost only arises in the use of variable not bound in the local frame ("free" variables). The process of finding the value of a free variable is called free variable lookup.

In a shallow bound system, the amount of cpu time required to fetch the value of a variable is constant regardless of whether the variable is local, special or global. The disadvantages of this scheme are that the actual binding of a variable takes longer (thus slowing down function call), the cells that contain the current in use values are spread throughout the space of all litatom value cells (thus increasing the working set size of functions) and context switching between processes requires unwinding and rewinding the stack (thus effectively prohibiting the use of context switching for many applications).

Interlisp-D uses deep binding, because of the working set considerations and the speed of context switching. The free variable lookup routine is microcoded, thus greatly reducing the search time. In benchman's, the largest percentage of free variable lookup time was 20 percent of the total ellapsed time; the normal time was between 5 and 10 percent.

One consequence of Interlisp-D's deep binding scheme is that users may significantly improve performance by declaring global variables in certain situations. If a variable is declared global, the

compiler will compile an access to that variable as a retrieval of its top level value, completely bypassing a stack search. This should be done only for variables that are never bound in functions, such as global databases and flags.

Global variable declarations should be done using the GLOBALVARS file package command (page 17.37). Its form is (GLOBALVARS  $VAR_1 \dots VAR_N$ ).

Another way of improving performance is to declare variables as local within a function. Normally, all variables bound within a function have their names put on the stack, and these names are scanned during free variable lookup. If a variable is declared to be local within a function, its name is not put on the stack, so it is not scanned during free variable lookup, which may increase the speed of lookups. The compiler can also make some other optimizations if a variable is known to be local to a function.

A variable may be declared as local within a function by including the form (DECLARE (LOCALVARS VAR<sub>1</sub> ... VAR<sub>N</sub>)) following the argument list in the definition of the function. Note: local variable declarations only effect the compilation of a function. Interpreted functions put all of their variable names on the stack, regardless of any declarations.

# 22.3 Performance Measuring

This section describes functions that gather and display statistics about a computation, such as as the elapsed time, and the number of data objects of different types allocated. TIMEALL and TIME gather statistics on the evaluation of a specified form. BREAKDOWN gathers statistics on individual functions called during a computation. These functions can be used to determine which parts of a computation are consuming the most resources (time, storage, etc.), and could most profitably be improved.

## (TIMEALL TIMEFORM NUMBEROFTIMES TIMEWHAT INTERPFLG —) [NLambda Function]

Evaluates the form *TIMEFORM* and prints statistics on time spent in various categories (elapsed, keyboard wait, swapping time, gc) and data type allocation.

For more accurate measurement on small computations, NUMBEROFTIMES may be specified (its default is 1) to cause TIMEFORM to be executed NUMBEROFTIMES times. To improve the accuracy of timing open-coded operations in this case, TIMEALL compiles a form to execute TIMEFORM NUMBEROFTIMES times (unless INTERPFLG is non-NIL), and then times the execution of the compiled form.

PERFORMANCE ISSUES 22.7

Note: If TIMEALL is called with NUMBEROFTIMES>1, the dummy form is compiled with compiler optimizations on. This means that it is not meaningful to use TIMEALL with very simple forms that are optimized out by the compiler. For example, (TIMEALL '(IPLUS 2 3) 1000) will time a compiled function which simply returns the number 5, since (IPLUS 2 3) is optimized to the integer 5.

TIMEWHAT restricts the statistics to specific categories. It can be an atom or list of datatypes to monitor, and/or the atom TIME to monitor time spent. Note that ordinarily, TIMEALL monitors all time and datatype usage, so this argument is rarely needed.

TIMEALL returns the value of the last evaluation of TIMEFORM.

## (TIME TIMEX TIMEN TIMETYP)

[NLambda Function]

**TIME** evaluates the form *TIMEX*, and prints out the number of **CONS** cells allocated and computation time. Garbage collection time is subtracted out. This function has been largely replaced by **TIMEALL**.

If *TIMEN* is greater than 1, *TIMEX* is executed *TIMEN* times, and **TIME** prints out (number of conses)/*TIMEN*, and (computation time)/*TIMEN*. If *TIMEN* = **NIL**, it defaults to 1. This is useful for more accurate measurement on small computations.

If *TIMETYP* is 0, **TIME** measures and prints total *real* time as well as computation time. If *TIMETYP* = 3, **TIME** measures and prints garbage collection time as well as computation time. If *TIMETYP* = T, TIME measures and prints the number of pagefaults.

TIME returns the value of the last evaluation of TIMEX.

## (BOXCOUNT TYPE N)

[Function]

Returns the number of data objects of type *TYPE* allocated since this Interlisp system was created. *TYPE* can be any data type name (see **TYPENAME**, page 8.20). If *TYPE* is **NIL**, it defaults to **FIXP**. If *N* is non-**NIL**, the corresponding counter is reset to *N*.

## (CONSCOUNT N)

[Function]

Returns the number of CONS cells allocated since this Interlisp system was created. If N is non-NIL, resets the counter to N. Equivalent to (BOXCOUNT 'LISTP N).

#### (PAGEFAULTS)

[Function]

Returns the number of page faults since this Interlisp system was created.

## 22.3.1 BREAKDOWN

**TIMEALL** collects statistics for whole computations. **BREAKDOWN** is available to analyze the breakdown of computation time (or any other measureable quantity) function by function.

## (BREAKDOWN FN1 ... FNN)

[NLambda NoSpread Function]

The user calls **BREAKDOWN** giving it a list of function names (unevaluated). These functions are modified so that they keep track of various statistics.

To remove functions from those being monitored, simply UNBREAK (page 15.7) the functions, thereby restoring them to their original state. To add functions, call BREAKDOWN on the new functions. This will not reset the counters for any functions not on the new list. However (BREAKDOWN) will zero the counters of all functions being monitored.

The procedure used for measuring is such that if one function calls other and both are "broken down", then the time (or whatever quantity is being measured) spent in the inner function is *not* charged to the outer function as well.

Note: BREAKDOWN will not give accurate results if a function being measured is not returned from normally, e.g., a lower RETFROM (or ERROR) bypasses it. In this case, all of the time (or whatever quantity is being measured) between the time that function is entered and the time the next function being measured is entered will be charged to the first function.

## (BRKDWNRESULTS RETURNVALUESFLG)

[Function]

BRKDWNRESULTS prints the analysis of the statistics requested as well as the number of calls to each function. If RETURNVALUESFLG is non-NIL, BRKDWNRESULTS will not to print the results, but instead return them in the form of a list of elements of the form (FNNAME #CALLS VALUE).

## Example:

← (BREAKDOWN SUPERPRINT SUBPRINT COMMENT1)

(SUPERPRINT SUBPRINT COMMENT1)

← (PRETTYDEF '(SUPERPRINT) 'FOO)

FOO.:3

← (BRKDWNRESULTS)

FUNCTIONS TIME #CALLS PER CALL %

SUPERPRINT 8.261 365 0.023 20

SUBPRINT 31.910 141 0.226 76

COMMENT1 1.612 8 0.201 4

TOTAL 41.783 514 0.081

NIL

← (BRKDWNRESULTS T) ((SUPERPRINT 365 8261) (SUBPRINT 141 31910) (COMMENT1 8 1612))

**BREAKDOWN** can be used to measure other statistics, by setting the following variables:

#### **BRKDWNTYPE**

[Variable]

To use BREAKDOWN to measure other statistics, before calling BREAKDOWN, set the variable BRKDWNTYPE to the quantity of interest, e.g., TIME, CONSES, etc, or a list of such quantities. Whenever BREAKDOWN is called with BRKDWNTYPE not NIL, BREAKDOWN performs the necessary changes to its internal state to conform to the new analysis. In particular, if this is the first time an analysis is being run with a particular statistic, a measuring function will be defined, and the compiler will be called to compile it. The functions being broken down will be redefined to call this measuring function. When BREAKDOWN is through initializing, it sets BRKDWNTYPE back to NIL. Subsequent calls to BREAKDOWN will measure the new statistic until BRKDWNTYPE is again set and a new BREAKDOWN performed.

#### **BRKDWNTYPES**

[Variable]

The list BRKDWNTYPES contains the information used to analyze new statistics. Each entry on BRKDWNTYPES should be of the form (TYPE FORM FUNCTION), where TYPE is a statistic name (as would appear in BRKDWNTYPE), FORM computes the statistic, and FUNCTION (optional) converts the value of form to some more interesting quantity. For example, (TIME (CLOCK 2) (LAMBDA (X) (FQUOTIENT X 1000))) measures computation time and reports the result in seconds instead of milliseconds. BRKDWNTYPES currently contains entries for TIME, CONSES, PAGEFAULTS, BOXES, and FBOXES.

## Example:

← (SETQ BRKDWNTYPE '(TIME CONSES))

(TIME CONSES)

← (BREAKDOWN MATCH CONSTRUCT)

(MATCH CONSTRUCT)

← (FLIP '(A B C D E F G H C Z) '(.. \$1 .. #2 ..) '(.. #3 ..))

(A B D E F G H Z)

← (BRKDWNRESULTS)

FUNCTIONS TIME #CALLS PER CALL %

MATCH 0.036 1 0.036 54

CONSTRUCT 0.031 1 0.031 46

TOTAL 0.067 2 0.033

FUNCTIONS CONSES #CALLS PER CALL %

MATCH 32 1 32.000 40 CONSTRUCT 49 1 49.000 60 TOTAL 81 2 40.500 NIL

Occasionally, a function being analyzed is sufficiently fast that the overhead involved in measuring it obscures the actual time spent in the function. If the user were using TIME, he would specify a value for TIMEN greater than 1 to give greater accuracy. A similar option is available for BREAKDOWN. The user can specify that a function(s) be executed a multiple number of times for each measurement, and the average value reported, by including a number in the list of functions given to BREAKDOWN, e.g., BREAKDOWN(EDITCOM EDIT4F 10 EDIT4E EQP) means normal breakdown for EDITCOM and EDIT4F but executes (the body of) EDIT4E and EQP 10 times each time they are called. Of course, the functions so measured must not cause any harmful side effects, since they are executed more than once for each call. The printout from BRKDWNRESULTS will look the same as though each function were run only once, except that the measurement will be more accurate.

Another way of obtaining more accurate measurement is to expand the call to the measuring function in-line. If the value of BRKDWNCOMPFLG is non-NIL (initially NIL), then whenever a function is broken-down, it will be redefined to call the measuring function, and then recompiled. The measuring function is expanded in-line via an appropriate macro. In addition, whenever BRKDWNTYPE is reset, the compiler is called for all functions for which BRKDWNCOMPFLG was set at the time they were originally broken-down, i.e. the setting of the flag at the time a function is broken-down determines whether the call to the measuring code is compiled in-line.

## 22.4 GAINSPACE

Users with large programs and data bases may sometimes find themselves in a situation where they needs to obtain more space, and are willing to pay the price of eliminating some or all of the context information that the various user-assistance facilities such as the programmer's assistant, file package, CLISP, etc., have accumulated during the course of his session. The function GAINSPACE provides an easy way to selectively throw away accumulated data:

(GAINSPACE)

[Function]

Prints a list of deletable objects, allowing the user to specify at each point what should be discarded and what should be retained. For example:

←(GAINSPACE)

purge history lists? Yes
purge everything, or just the properties, e.g., SIDE, LISPXPRINT,
etc.?
just the properties
discard definitions on property lists? Yes
discard old values of variables? Yes
erase properties? No
erase CLISP translations? Yes

GAINSPACE is driven by the list GAINSPACEFORMS. Each element on GAINSPACEFORMS is of the form (PRECHECK MESSAGE FORM KEYLST). If PRECHECK, when evaluated, returns NIL, GAINSPACE skips to the next entry. For example, the user will not be asked whether or not to purge the history list if it is not enabled. Otherwise, ASKUSER (page 26.12) is called with the indicated MESSAGE and the (optional) KEYLST. If the user responds No, i.e., ASKUSER returns N, GAINSPACE skips to the next entry. Otherwise, FORM is evaluated with the variable RESPONSE bound to the value of ASKUSER. In the above example, the FORM for the "purge history lists" question calls ASKUSER to ask "purge everything, ..." only if the user had responded Yes. If the user had responded with Everything, the second question would not have been asked.

The "erase properties" question is driven by a list SMASHPROPSMENU. Each element on this list is of the form (MESSAGE . PROPS). The user is prompted with MESSAGE (by ASKUSER), and if he responds Yes, PROPS is added to the list SMASHPROPS. The "discard definitions on property lists" and "discard old values of variables" questions also add to SMASHPROPS. The user will not be prompted for any entry on SMASHPROPSMENU for which all of the corresponding properties are already on SMASHPROPS. **SMASHPROPS** is initially set to the value of SMASHPROPSLST. This permits the user to specify in advance those properties which he always wants to be discarded, and not be asked about them subsequently. After finishing all the entries GAINSPACEFORMS, GAINSPACE checks to see if the value of SMASHPROPS is non-NIL, and if so, does a MAPATOMS, i.e., looks at every atom in the system, and erases the indicated properties.

Note that the user can change or add new entries to GAINSPACEFORMS or SMASHPROPSMENU, so that GAINSPACE

can also be used to purge structures that the user's programs have accumulated.

# 22.5 Using Data Types Instead of Records

If a program uses large numbers of large data structures, there are several advantages to representing them as user data types rather than as list structures. The primary advantage is increased speed: accessing and setting the fields of a data type can be significantly faster than walking through a list with repeated CARs and CDRs. Also, compiled code for referencing data types is usually smaller. Finally, by reducing the number of objects created (one object against many list cells), this can reduce the expense of garbage collection.

User data types are declared by using the DATATYPE record type (page 8.9). If a list structure has been defined using the RECORD record type (page 8.7), and all accessing operations are written using the record package's fetch, replace, and create operations, changing from RECORDs to DATATYPEs only requires editing the record declaration (using EDITREC, page 8.16) to replace declaration type RECORD by DATATYPE, and recompiling.

Note: There are some minor disadvantages with allocating new data types: First, there is an upper limit on the number of data types which can exist. Also, space for data types is allocated a page at a time, so each data type has at least one page assigned to it, which may be wasteful of space if there are only a few examples of a given data type. These problems should not effect most applications programs.

# 22.6 Using Incomplete File Names

Currently, Interlisp allows you to specify an open file by giving the file name. If the file name is incomplete (it doesn't have the device/host, directory, name, extension, and version number all supplied), the system converts it to a complete file name, by supplying defaults and searching through directories (which may be on remote file servers), and then searches the open streams for one corresponding to that file name. This file name-completion process happens whenever any I/O function is given an incomplete file name, which can cause a serious performance problem if I/O operations are done repeatedly. In general, it is much faster to convert an incomplete file name to a stream once, and use the stream from then on. For example,

PERFORMANCE ISSUES 22.13

suppose a file is opened with (SETQ STRM (OPENSTREAM 'MYNAME 'INPUT)). After doing this, (READC 'MYNAME) and (READC STRM) would both work, but (READC 'MYNAME) would take longer (sometimes orders of magnitude longer). This could seriously effect the performance if a program which is doing many I/O operations.

Note: At some point in the future, when multiple streams are supported to a single file, the feature of mapping file names to streams will be removed. This is yet another reason why programs should use streams as handles to open files, instead of file names.

For more information on efficiency considerations when using files, see page 24.13.

# 22.7 Using "Fast" and "Destructive" Functions

Among the functions used for manipulating objects of various data types, there are a number of functions which have "fast" and "destructive" versions. The user should be aware of what these functions do, and when they should be used.

"Fast" functions: By convention, a function named by prefixing an existing function name with F indicates that the new function is a "fast" version of the old. These usually have the same definitions as the slower versions, but they compile open and run without any "safety" error checks. For example, FNTH runs faster than NTH, however, it does not make as many checks (for lists ending with anything but NIL, etc). If these functions are given arguments that are not in the form that they expect, their behavior is unpredictable; they may run forever, or cause a system error. In general, the user should only use "fast" functions in code that has already been completely debugged, to speed it up.

"Destructive" functions: By convention, a function named by prefixing an existing function with **D** indicates the new function is a "destructive" version of the old one, which does not make any new structure but cannibalizes its argument(s). For example, **REMOVE** returns a copy of a list with a particular element removed, but **DREMOVE** actually changes the list structure of the list. (Unfortunately, not all destructive functions follow this naming convention: the destructive version of **APPEND** is **NCONC.**) The user should be careful when using destructive functions that they do not inadvertantly change data structures.

[This page intentionally left blank]

TOC.2 TABLE OF CONTENTS

The Interlisp-D Process mechanism provides an environment in which multiple Lisp processes can run in parallel. Each executes in its own stack space, but all share a global address space. The current process implementation is cooperative; i.e., process switches happen voluntarily, either when the process in control has nothing to do or when it is in a convenient place to pause. There is no preemption or guaranteed service, so you cannot run something demanding (e.g., Chat) at the same time as something that runs for long periods without yielding control. Keyboard input and network operations block with great frequency, so processes currently work best for highly interactive tasks (editing, making remote files).

In Interlisp-D, the process mechanism is already turned on, and is expected to stay on during normal operations, as some system facilities (in particular, most network operations) require it. However, under exceptional conditions, the following function can be used to turn the world off and on:

## (PROCESSWORLD FLG)

[Function]

Starts up the process world, or if *FLG* = OFF, kills all processes and turns it off. Normally does not return. The environment starts out with two processes: a top-level EVALQT (the initial "tty" process) and the "background" process, which runs the window mouse handler and other system background tasks.

Note: PROCESSWORLD is intended to be called at the top level of Interlisp, not from within a program. It does not toggle some sort of switch; rather, it constructs some new processes in a new part of the stack, leaving any callers of PROCESSWORLD in a now inaccessible part of the stack. Calling (PROCESSWORLD 'OFF) is the only way the call to PROCESSWORLD ever returns.

## (HARDRESET)

[Function]

Resets the whole world, and rebuilds the stack from scratch. This is "harder" than doing RESET to every process, because it also resets system internal processes (such as the keyboard handler).

HARDRESET automatically turns the process world on (or resets it if it was on), unless the variable AUTOPROCESSFLG is NIL.

# 23.1 Creating and Destroying Processes

## (ADD.PROCESS FORM PROP<sub>1</sub> VALUE<sub>1</sub> ... PROP<sub>N</sub> VALUE<sub>N</sub>)

[NoSpread Function]

Creates a new process evaluating *FORM*, and returns its process handle. The process's stack environment is the top level, i.e., the new process does not have access to the environment in which **ADD.PROCESS** was called; all such information must be passed as arguments in *FORM*. The process runs until *FORM* returns or the process is explicitly deleted. An untrapped error within the process also deletes the process (unless its **RESTARTABLE** property is **T**), in which case a message is printed to that effect.

The remaining arguments are alternately property names and values. Any property/value pairs acceptable to PROCESSPROP may be given, but the following two are directly relevant to ADD.PROCESS:

#### NAME

Value should be a litatom; if not given, the process name is taken from (CAR FORM). ADD.PROCESS may pack the name with a number to make it unique. This name is solely for the convenience of manipulating processes at Lisp typein; e.g., the name can be given as the PROC argument to most process functions, and the name appears in menus of processes. However, programs should normally only deal in process handles, both for efficiency and to avoid the confusion that can result if two processes have the same defining form.

## SUSPEND

If the value is non-NIL, the new process is created but then immediately suspended; i.e., the process does not actually run until woken by a WAKE.PROCESS (below).

## (PROCESSPROP PROC PROP NEWVALUE)

[NoSpread Function]

Used to get or set the values of certain properties of process *PROC*, in a manner analogous to **WINDOWPROP**. If *NEWVALUE* is supplied (including if it is **NIL**), property *PROP* is given that value. In all cases, returns the old value of the property. The following properties have special meaning for processes; all others are uninterpreted:

NAME

Value is a litatom used for identifying the process to the user.

FORM

Value is the Lisp form used to start the process (readonly).

#### RESTARTABLE

Value is a flag indicating the disposition of the process following errors or hard resets:

NIL or NO (the default): If an untrapped error (or control-E or control-D) causes its form to be exited, the process is deleted. The process is also deleted if a HARDRESET (or control-D from RAID) occurs, causing the entire Process world to be reinitialized.

T or YES: The process is automatically restarted on errors or HARDRESET. This is the normal setting for persistent

"background" processes, such as the mouse process, that can safely restart themselves on errors.

HARDRESET: The process is deleted as usual if an error causes its form to be exited, but it is restarted on a HARDRESET. This setting is preferred for persistent processes for which an error is an unusual condition, one that might repeat itself if the process were simply blindly restarted.

#### RESTARTFORM

If the value is non--NIL, it is the form used if the process is restarted (instead of the value of the FORM property). Of course, the process must also have a non-NIL RESTARTABLE prop for this to have any effect.

#### **BEFOREEXIT**

If the value is the atom **DON'T**, it will not be interrupted by a **LOGOUT**. If **LOGOUT** is attempted before the process finishes, a message will appear saying that Interlisp is waiting for the process to finish. If you want the **LOGOUT** to proceed without waiting, you must use the process status window (from the background menu) to delete the process.

#### **AFTEREXIT**

Value indicates the disposition of the process following a resumption of Lisp after some exit (LOGOUT, SYSOUT, MAKESYS). Possible values are:

**DELETE**: Delete the process.

**SUSPEND:** Suspend the process; i.e., do not let it run until it is explicitly woken.

An event: Cause the process to be suspended waiting for the event (page 23.7).

## **INFOHOOK**

Value is a function or form used to provide information about the process, in conjunction with the INFO command in the process status window (page 23.16).

## WINDOW

Value is a window associated with the process, the process's "main" window. Used to switch the tty process to this process when the user clicks in this window (see page 23.12).

Note: Setting the WINDOW property does not set the primary i/o stream (NIL) or the terminal i/o stream (T) to the window. When a process is created, i/o operations to the NIL or T stream will cause a new window to appear. TTYDISPLAYSTREAM (page 28.29) should be used to set the terminal i/o stream of a process to a specific window.

#### **TTYENTRYFN**

Value is a function that is applied to the process when the process is made the tty process (page 23.13).

#### **TTYEXITFN**

Value is a function that is applied to the process when the process ceases to be the tty process (page 23.13).

## (THIS.PROCESS)

[Function]

Returns the handle of the currently running process, or **NIL** if the **Process** world is turned off.

## (DEL.PROCESS PROC —)

[Function]

Deletes process *PROC*. *PROC* may be a process handle (returned by ADD.PROCESS), or its name. Note that if *PROC* is the currently running process, DEL.PROCESS does not return!

## (PROCESS.RETURN VALUE)

[Function]

Terminates the currently running process, causing it to "return" *VALUE*. There is an implicit **PROCESS.RETURN** around the *FORM* argument given to **ADD.PROCESS**, so that normally a process can finish by simply returning; **PROCESS.RETURN** is supplied for earlier termination.

## (PROCESS.RESULT PROCESS WAITFORRESULT)

[Function]

If PROCESS has terminated, returns the value, if any, that it returned. This is either the value of a PROCESS.RETURN or the value returned from the form given to ADD.PROCESS. If the process was aborted, the value is NIL. If WAITFORRESULT is true, PROCESS.RESULT blocks until PROCESS finishes, if necessary; otherwise, it returns NIL immediately if PROCESS is still running. Note that PROCESS must be the actual process handle returned from ADD.PROCESS, not a process name, as the association between handle and name disappears when the process finishes (and the process handle itself is then garbage collected if no one else has a pointer to it).

## (PROCESS.FINISHEDP PROCESS)

[Function]

True if *PROCESS* has terminated. The value returned is an indication of how it finished: **NORMAL** or **ERROR**.

## (PROCESSP PROC)

[Function]

True if *PROC* is the handle of an active process, i.e., one that has not yet finished.

## (RELPROCESSP PROCHANDLE)

[Function]

True if *PROCHANDLE* is the handle of a deleted process. This is analogous to *RELSTKP*. It differs from *PROCESS.FINISHEDP* in that it never causes an error, while *PROCESS.FINISHEDP* can cause an error if its *PROC* argument is not a process at all.

#### (RESTART.PROCESS PROC)

[Function]

Unwinds *PROC* to its top level and reevaluates its form. This is effectively a **DEL.PROCESS** followed by the original **ADD.PROCESS**.

## (MAP.PROCESSES MAPFN)

[Function]

Maps over all processes, calling MAPFN with three arguments: the process handle, its name, and its form.

## (FIND.PROCESS PROCERRORFLG)

[Function]

If *PROC* is a process handle or the name of a process, returns the process handle for it, else **NIL**. If *ERRORFLG* is T, generates an error if *PROC* is not, and does not name, a live process.

## 23.2 Process Control Constructs

## (BLOCK MSECSWAIT TIMER)

[Function]

Yields control to the next waiting process, assuming any is ready to run. If MSECSWAIT is specified, it is a number of milliseconds to wait before returning, or T, meaning wait forever (until explicitly woken). Alternatively, TIMER can be given as a millisecond timer (as returned by SETUPTIMER, page 12.17) of an absolute time at which to wake up. In any of those cases, the process enters the waiting state until the time limit is up. BLOCK with no arguments leaves the process in the runnable state, i.e., it returns as soon as every other runnable process of the same priority has had a chance.

**BLOCK** can be aborted by interrupts such as control-D, control-E, or control-B. Note that **BLOCK** will return before its timeout is completed, if the process is woken by **WAKE.PROCESS**, **PROCESS.EVAL**, or **PROCESS.APPLY**.

## (DISMISS MSECSWAIT TIMER NOBLOCK)

[Function]

DISMISS is used to dismiss the current process for a given period of time. Similar to BLOCK, except that (1) DISMISS is guaranteed not to return until the specified time has elapsed; (2) MSECSWAIT cannot be T to wait forever; and (3) If NOBLOCK is T, DISMISS will not allow other processes to run, but will busy-wait until the amount of time given has elapsed.

## (WAKE.PROCESS PROC STATUS)

[Function]

Explicitly wakes process *PROC*, i.e., makes it *runnable*, and causes its call to **BLOCK** (or other waiting function) to return *STATUS*.

This is one simple way to notify a process of some happening; however, note that if **WAKE.PROCESS** is applied to a process more than once before the process actually gets its turn to run, it sees only the latest *STATUS*.

## (SUSPEND.PROCESS PROC)

[Function]

Blocks process *PROC* indefinitely, i.e., *PROC* will not run until it is woken by a **WAKE.PROCESS**.

The following three functions allow access to the stack context of some other process. They require a little bit of care, and are computationally non-trivial, but they do provide a more powerful way of manipulating another process than WAKE.PROCESS allows.

## (PROCESS.EVALV PROC VAR)

[Function]

Performs (EVALV VAR) in the stack context of PROC.

## (PROCESS.EVAL PROC FORM WAITFORRESULT)

[Function]

Evaluates *FORM* in the stack context of *PROC*. If *WAITFORRESULT* is true, blocks until the evaluation returns a result, else allows the current process to run in parallel with the evaluation. Any errors that occur will be in the context of *PROC*, so be careful. In particular, note that

(PROCESS.EVAL PROC'(NLSETQ (FOO)))

and

(NLSETQ (PROCESS.EVAL PROC'(FOO)))

behave quite differently if FOO causes an error. And it is quite permissible to intentionally cause an error in proc by performing

(PROCESS.EVAL PROC'(ERROR!))

If errors are possible and WAITFORRESULT is true, the caller should almost certainly make sure that FORM traps the errors; otherwise the caller could end up waiting forever if FORM unwinds back into the pre-existing stack context of PROC.

Note: After FORM is evaluated in PROC, the process PROC is woken up, even if it was running BLOCK or AWAIT.EVENT. This is necessary because an event of interest may have occurred while the process was evaluating FORM.

#### (PROCESS.APPLY PROC FN ARGS WAITFORRESULT)

[Function]

Performs (APPLY FN ARGS) in the stack context of PROC. Note the same warnings as with PROCESS.EVAL.

## 23.3 Events

An "event" is a synchronizing primitive used to coordinate related processes, typically producers and consumers. Consumer processes can "wait" on events, and producers "notify" events.

## (CREATE.EVENT NAME)

[Function]

Returns an instance of the **EVENT** datatype, to be used as the event argument to functions listed below. *NAME* is arbitrary, and is used for debugging or status information.

## (AWAIT.EVENT EVENT TIMEOUT TIMERP)

[Function]

Suspends the current process until EVENT is notified, or until a timeout occurs. If TIMEOUT is NIL, there is no timeout. Otherwise, timeout is either a number of milliseconds to wait, or, if TIMERP is T, a millisecond timer set to expire at the desired time using SETUPTIMER (see page 12.16).

## (NOTIFY.EVENT EVENT ONCEONLY)

[Function]

If there are processes waiting for *EVENT* to occur, causes those processes to be placed in the running state, with *EVENT* returned as the value from **AWAIT.EVENT**. If *ONCEONLY* is true, only runs the first process waiting for the event (this should only be done if the programmer knows that there can only be one process capable of responding to the event at once).

The meaning of an event is up to the programmer. In general, however, the notification of an event is merely a hint that something of interest to the waiting process has happened; the process should still verify that the conceptual event actually occurred. That is, the process should be written so that it operates correctly even if woken up before the timeout and in the absence of the notified event. In particular, the completion of PROCESS.EVAL and related operations in effect wakes up the process in which they were performed, since there is no secure way of knowing whether the event of interest occurred while the process was busy performing the PROCESS.EVAL.

There is currently one class of system-defined events, used with the network code. Each Pup and NS socket has associated with it an event that is notified when a packet arrives on the socket; the event can be obtained by calling PUPSOCKETEVENT (page 31.29) or NSOCKETEVENT (page 31.37), respectively.

## 23.4 Monitors

It is often the case that cooperating processes perform operations on shared structures, and some mechanism is needed to prevent more than one process from altering the structure at the same time. Some languages have a construct called a monitor, a collection of functions that access a common structure with mutual exclusion provided and enforced by the compiler via the use of monitor locks. Interlisp-D has taken this implementation notion as the basis for a mutual exclusion capability suitable for a dynamically-scoped environment.

A monitorlock is an object created by the user and associated with (e.g., stored in) some shared structure that is to be protected from simultaneous access. To access the structure, a program waits for the lock to be free, then takes ownership of the lock, accesses the structure, then releases the lock. The functions and macros below are used:

## (CREATE.MONITORLOCK NAME —)

[Function]

Returns an instance of the MONITORLOCK datatype, to be used as the lock argument to functions listed below. *NAME* is arbitrary, and is used for debugging or status information.

## (WITH.MONITOR LOCK FORM $_1$ ... FORM $_N$ )

[Macro]

Evaluates  $FORM_1$  ...  $FORM_N$  while owning LOCK, and returns the value of  $FORM_N$ . This construct is implemented so that the lock is released even if the form is exited via error (currently implemented with RESETLST).

Ownership of a lock is dynamically scoped: if the current process already owns the lock (e.g., if the caller was itself inside a **WITH.MONITOR** for this lock), **WITH.MONITOR** does not wait for the lock to be free before evaluating  $FORM_1 \dots FORM_N$ .

## (WITH.FAST.MONITOR LOCK FORM 1 ... FORM N)

[Macro]

Like WITH.MONITOR, but implemented without the RESETLST. User interrupts (e.g., control-E) are inhibited during the evaluation of  $FORM_1 \dots FORM_N$ .

Programming restriction: the evaluation of  $FORM_1$  ...  $FORM_N$  must not error (the lock would not be released). This construct is mainly useful when the forms perform a small, safe computation that never errors and need never be interrupted.

#### (MONITOR.AWAIT.EVENT RELEASELOCK EVENT TIMEOUT TIMERP)

[Function]

For use in blocking inside a monitor. Performs (AWAIT.EVENT EVENT TIMEOUT TIMERP), but releases RELEASELOCK first, and reobtains the lock (possibly waiting) on wakeup.

Typical use for MONITOR.AWAIT.EVENT: A function wants to perform some operation on *FOO*, but only if it is in a certain state. It has to obtain the lock on the structure to make sure that the state of the structure does not change between the time it tests the state and performs the operation. If the state turns out to be bad, it then waits for some other process to make the state good, meanwhile releasing the lock so that the other process can alter the structure.

(WITH.MONITOR FOO-LOCK

(until CONDITION-OF-FOO

do (MONITOR.AWAIT.EVENT FOO-LOCK

EVENT-FOO-CHANGED TIMEOUT))

OPERATE-ON-FOO)

It is sometimes convenient for a process to have WITH.MONITOR at its top level and then do all its interesting waiting using MONITOR.AWAIT.EVENT. Not only is this often cleaner, but in the present implementation in cases where the lock is frequently accessed, it saves the RESETLST overhead of WITH.MONITOR.

Programming restriction: There must not be an ERRORSET between the enclosing WITH.MONITOR and the call to MONITOR.AWAIT.EVENT such that the ERRORSET would catch an ERROR! and continue inside the monitor, for the lock would not have been reobtained. (The reason for this restriction is that, although MONITOR.AWAIT.EVENT won't itself error, the user could have caused an error with an interrupt, or a PROCESS.EVAL in the context of the waiting process that produced an error.)

On rare occasions it may be useful to manipulate monitor locks directly. The following two functions are used in the implementation of WITH.MONITOR:

## (OBTAIN.MONITORLOCK LOCK DONTWAIT UNWINDSAVE)

[Function]

Takes possession of *LOCK*, waiting if necessary until it is free, unless *DONTWAIT* is true, in which case it returns **NIL** immediately. If *UNWINDSAVE* is true, performs a **RESETSAVE** to be unwound when the enclosing **RESETLST** exits. Returns *LOCK* if *LOCK* was successfully obtained, T if the current process already owned *LOCK*.

#### (RELEASE.MONITORLOCK LOCK EVENIFNOTMINE)

[Function]

Releases LOCK if it is owned by the current process, and wakes up the next process, if any, waiting to obtain the lock.

If *EVENIFNOTMINE* is non-NIL, the lock is released even if it is not owned by the current process.

When a process is deleted, any locks it owns are released.

## 23.5 Global Resources

The biggest source of problems in the multi-processing environment is the matter of global resources. Two processes cannot both use the same global resource if there can be a process switch in the middle of their use (currently this means calls to **BLOCK**, but ultimately with a preemptive scheduler means anytime). Thus, user code should be wary of its own use of global variables, if it ever makes sense for the code to be run in more than one process at a time. "State" variables private to a process should generally be bound in that process; structures that are shared among processes (or resources used privately but expensive to duplicate per process) should be protected with monitor locks or some other form of synchronization.

Aside from user code, however, there are many system global variables and resources. Most of these arise historically from the single-process Interlisp-10 environment, and will eventually be changed in Interlisp-D to behave appropriately in a multi-processing environment. Some have already been changed, and are described below. Two other resources not generally thought of as global variables—the keyboard and the mouse—are particularly idosyncratic, and are discussed in the next section.

The following resources, which are global in Interlisp-10, are allocated per process in Interlisp-D: primary input and output (the streams affected by INPUT and OUTPUT), terminal input and output (the streams designated by the name T), the primary read table and primary terminal table, and dribble files. Thus, each process can print to its own primary output, print to the terminal, read from a different primary input, all without interfering with another process's reading and printing.

Each process begins life with its primary and terminal input/output streams set to a dummy stream. If the process attempts input or output using any of those dummy streams, e.g., by calling (READ T), or (PRINT & T), a tty window is automatically created for the process, and that window becomes the primary input/output and terminal input/output for the process. The default tty window is created at or near the region specified in the variable DEFAULTTTYREGION.

A process can, of course, call TTYDISPLAYSTREAM explicitly to give itself a tty window of its own choosing, in which case the automatic mechanism never comes into play. Calling TTYDISPLAYSTREAM when a process has no tty window not only sets the terminal streams, but also sets the primary input and output streams to be that window, assuming they were still set to the dummy streams.

Returns T if the process *PROCESS* has a tty window; **NIL** otherwise. If *PROCESS* is **NIL**, it defaults to the current process.

Other system resources that are typically changed by RESETFORM, RESETLST, or RESETVARS are all global entities. In the multiprocessing environment, these constructs are suspect, as there is no provision for "undoing" them when a process switch occurs. For example, in the current release of Interlisp-D, it is not possible to set the print radix to 8 inside only one process, as the print radix is a global entity.

Note that RESETFORM and similar expressions are perfectly valid in the process world, and even quite useful, when they manipulate things strictly within one process. The process world is arranged so that deleting a process also unwinds any RESETxxx expressions that were performed in the process and are still waiting to be unwound, exactly as if a control-D had reset the process to the top. Additionally, there is an implicit RESETLST at the top of each process, so that RESETSAVE can be used as a way of providing "cleanup" functions for when a process is deleted. For these, the value of RESETSTATE (page 14.26) is NIL if the process finished normally, ERROR if it was aborted by an error, RESET if the process was explicitly deleted, and HARDRESET if the process is being restarted after a HARDRESET or a RESTART.PROCESS.

# 23.6 Typein and the TTY Process

There is one global resource, the keyboard, that is particularly problematic to share among processes. Consider, for example, having two processes both performing (READ T). Since the keyboard input routines block while there is no input, both processes would spend most of their time blocking, and it would simply be a matter of chance which process received each character of typein.

To resolve such dilemmas, the system designates a distinguished process, termed the *tty process*, that is assumed to be the process that is involved in terminal interaction. Any typein from the keyboard goes to that process. If a process other than the tty process requests keyboard input, it blocks until it becomes the tty process. When the tty process is switched (in any of the ways described further below), any typeahead that occurred before the switch is saved and associated with the current tty process. Thus, it is always the case that keystrokes are sent to the process

that is the tty process at the time of the keystrokes, regardless of when that process actually gets around to reading them.

It is less immediately obvious how to handle keyboard interrupt characters, as their action is asynchronous and not always tied to typein. Interrupt handling is described on page 23.14.

## 23.6.1 Switching the TTY Process

Any process can make itself be the tty process by calling TTY.PROCESS.

## (TTY.PROCESS PROC)

[Function]

Returns the handle of the current tty process. In addition, if *PROC* is non-NIL, makes it be the tty process. The special case of *PROC* = T is interpreted to mean the executive process; this is sometimes useful when a process wants to explicitly give up being the tty process.

## (TTY.PROCESSP PROC)

[Function]

True if *PROC* is the tty process; *PROC* defaults to the running process. Thus, (TTY.PROCESSP) is true if the caller is the tty process.

#### (WAIT.FOR.TTY MSECS NEEDWINDOW)

[Function]

Efficiently waits until (TTY.PROCESSP) is true. WAIT.FOR.TTY is called internally by the system functions that read from the terminal; user code thus need only call it in special cases.

If MSECS is non-NIL, it is the number of milliseconds to wait before timing out. If WAIT.FOR.TTY times out before (TTY.PROCESSP) is true, it returns NIL, otherwise it returns T. If MSECS is NIL, WAIT.FOR.TTY will not time out.

If **NEEDWINDOW** is non-**NIL**, **WAIT.FOR.TTY** opens a TTY window for the current process if one isn't already open.

**WAIT.FOR.TTY** spawns a new mouse process if called under the mouse process (see **SPAWN.MOUSE**, page 23.15).

In some cases, such as in functions invoked as a result of mouse action or a user's typed-in call, it is reasonable for the function to invoke TTY.PROCESS itself so that it can take subsequent user type in. In other cases, however, this is too undisciplined; it is desirable to let the user designate which process typein should be directed to. This is most conveniently done by mouse action.

The system supports the model that "to type to a process, you click in its window." To cooperate with this model, any process desiring keyboard input should put its process handle as the

PROCESS property of its window(s). To handle the common case, the function TTYDISPLAYSTREAM does this automatically when the ttydisplaystream is switched to a new window. A process can own any number of windows; clicking in any of those windows gives the process the tty.

This mechanism suffices for most casual process writers. For example, if a process wants all its input/output interaction to occur in a particular window that it has created, it should just make that window be its tty window by calling TTYDISPLAYSTREAM. Thereafter, it can PRINT or READ to/from the T stream; if the process is not the tty process at the time that it calls READ, it will block until the user clicks in the window.

For those needing tighter control over the tty, the default behavior can be overridden or supplemented. The remainder of this section describes the mechanisms involved.

There is a window property WINDOWENTRYFN that controls whether and how to switch the tty to the process owning a window. The mouse handler, before invoking any normal BUTTONEVENTFN, specifically notices the case of a button going down in a window that belongs to a process (i.e., has a PROCESS window property) that is not the tty process. In this case, it invokes the window's WINDOWENTRYFN of one argument (WINDOW). WINDOWENTRYFN defaults to GIVE.TTY.PROCESS:

## (GIVE.TTY.PROCESS WINDOW)

[Function]

If WINDOW has a PROCESS property, performs (TTY.PROCESS (WINDOWPROP WINDOW 'PROCESS)) and then invokes WINDOW'S BUTTONEVENTEN function (or RIGHTBUTTONEN if the right button is down).

There are some cases where clicking in a window does not always imply that the user wants to talk to that window. For example, clicking in a text editor window with a shift key held down means to "shift-select" some piece of text into the input buffer of the *current* tty process. The editor supports this by supplying a WINDOWENTRYFN that performs GIVE.TTY.PROCESS if no shift key is down, but goes into its shift-select mode, without changing the tty process, if a shift key is down. The shift-select mode performs a BKSYSBUF of the selected text when the shift key is let up, the BKSYSBUF feeding input to the current tty process.

Sometimes a process wants to be notified when it becomes the tty process, or stops being the tty process. To support this, there are two process properties, TTYEXITFN and TTYENTRYFN. The actions taken by TTY.PROCESS when it switches the tty to a new process are as follows: the former tty process's TTYEXITFN is called with two arguments (OLDTTYPROCESS NEWTTYPROCESS);

the new process is made the tty process; finally, the new tty process's TTYENTRYFN is called with two arguments (NEWTTYPROCESS). Normally the TTYENTRYFN and TTYEXITFN need only their first argument, but the other process involved in the switch is supplied for completeness. In the present system, most processes want to interpret the keyboard in the same way, so it is considered the responsibility of any process that changes the keyboard interpretation to restore it to the normal state by its TTYEXITFN.

A window is "owned" by the last process that anyone gave as the window's PROCESS property. Ordinarily there is no conflict here, as processes tend to own disjoint sets of windows (though, of course, cooperating processes can certainly try to confuse each other). The only likely problem arises with that most global of windows, PROMPTWINDOW. Programs should not be tempted to read from PROMPTWINDOW. This is not usually necessary anyway, as the first attempt to read from T in a process that has not set its TTYDISPLAYSTREAM to its own window causes a tty window to be created for the process (see page 23.10).

## 23.6.2 Handling of Interrupts

At the time that a keyboard interrupt character (page 30.1) is struck, any process could be running, and some decision must be made as to which process to actually interrupt. To the extent that keyboard interrupts are related to typein, most interrupts are taken in the tty process; however, the following are handled specially:

# RESET (initially control-D) ERROR (initially control-E)

These interrupts are taken in the mouse process, if the mouse is not in its idle state; otherwise they are taken in the tty process. Thus, control-E can be used to abort some mouse-invoked window action, such as the Shape command. As a consequence, note that if the mouse invokes some lengthy computation that the user thinks of as "background", control-E still aborts it, even though that may not have been what the user intended. Such lengthy computations, for various reasons, should generally be performed by spawning a separate process to perform them.

The **RESET** interrupt in a process other than the executive is interpreted exactly as if an error unwound the process to its top level: if the process was designated **RESTARTABLE** = **T**, it is restarted; otherwise it is killed.

## **HELP** (initially control-G)

A menu of processes is presented to the user, who is asked to select which one the interrupt should occur in. The current tty process appears with a \* next to its name at the top of the menu. The menu also includes an entry "[Spawn Mouse]", for the common case of needing a mouse because the mouse process is

currently tied up running someone's **BUTTONEVENTFN**; selecting this entry spawns a new mouse process, and no break occurs.

**BREAK** (initially control-B)

Performs the **HELP** interrupt in the mouse process, if the mouse is not in its idle state; otherwise it is performed in the tty process.

**RUBOUT** (initially DELETE)

This interrupt clears typeahead in all processes.

RAID STACK OVERFLOW STORAGE FULL

These interrupts always occur in whatever process was running at the time the interrupt struck. In the cases of STACK OVERFLOW and STORAGE FULL, this means that the interrupt is more likely to strike in the offending process (especially if it is a "runaway" process that is not blocking). Note, however, that this process is still not necessarily the guilty party; it could be an innocent bystander that just happened to use up the last of a resource prodigiously consumed by some other process.

## 23.7 Keeping the Mouse Alive

Since the window mouse handler runs in its own process, it is not available while a window's BUTTONEVENTFN function (or any of the other window functions invoked by mouse action) is running. This leads to two sorts of problems: (1) a long computation underneath a BUTTONEVENTFN deprives the user of the mouse for other purposes, and (2) code that runs as a BUTTONEVENTFN cannot rely on other BUTTONEVENTFNs running, which means that there some pieces of code that run differently from normal when run under the mouse process. These problems are addressed by the following functions:

#### (SPAWN.MOUSE —)

[Function]

Spawns another mouse process, allowing the mouse to run even if it is currently "tied up" under the current mouse process. This function is intended mainly to be typed in at the Lisp executive when the user notices the mouse is busy.

## (ALLOW.BUTTON.EVENTS)

[Function]

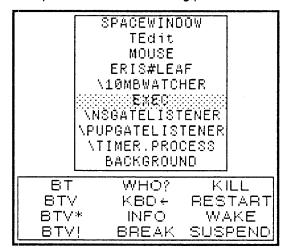

Performs a (SPAWN.MOUSE) only when called underneath the mouse process. This should be called (once, on entry) by any function that relies on **BUTTONEVENTFNs** for completion, if there is any possibility that the function will itself be invoked by a mouse function.

It never hurts, at least logically, to call SPAWN.MOUSE or ALLOW.BUTTON.EVENTS needlessly, as the mouse process

arranges to quietly kill itself if it returns from the user's **BUTTONEVENTFN** and finds that another mouse process has sprung up in the meantime. (There is, of course, some computational expense.)

## 23.8 Process Status Window

The background menu command PSW (page 28.6) and the function PROCESS.STATUS.WINDOW (below) create a "Process Status Window", that allows the user to examine and manipulate all of the existing processes:

The window consists of two menus. The top menu lists all the processes at the moment. Commands in the bottom menu operate on the process selected in the top menu (EXEC in the example above). The commands are:

BT, BTV, BTV\*, BTV!

Displays a backtrace of the selected process.

WHO?

Changes the selection to the tty process, i.e., the one currently in control of the keyboard.

KBD←

Associates the keyboard with the selected process; i.e., makes the selected process be the tty process.

INFO

If the selected process has an INFOHOOK property, calls it. The hook may be a function, which is then applied to two arguments, the process and the button (LEFT or MIDDLE) used to invoke INFO, or a form, which is simply EVAL'ed. The APPLY or EVAL happens in the context of the selected process, using PROCESS.APPLY or PROCESS.EVAL. The INFOHOOK process property can be set using PROCESSPROP (page 23.2).

BREAK

Enter a break under the selected process. This has the side effect of waking the process with the value returned from the break.

KILL

Deletes the selected process.

**RESTART** Restarts the selected process.

WAKE Wakes the selected process. Prompts for a value to wake it with

(see WAKE.PROCESS).

SUSPEND Suspends the selected process; i.e., causes it to block indefinitely

(until explicitly woken).

## (PROCESS.STATUS.WINDOW WHERE)

[Function]

Puts up a process status window that provides several debugging commands for manipulating running processes. If the window is already up, **PROCESS.STATUS.WINDOW** refreshes it. If *WHERE* is a position, the window is placed in that position; otherwise, the user is prompted for a position.

Currently, the process status window runs under the mouse process, like other menus, so if the mouse is unavailable (e.g., a mouse function is performing an extensive computation), you may be unable to use the process status window (you can try SPAWN.MOUSE, of course).

# 23.9 Non-Process Compatibility

This section describes some considerations for authors of programs that ran in the old single-process Interlisp-D environment, and now want to make sure they run properly in the Multi-processing world. The biggest problem to watch out for is code that runs underneath the mouse handler. Writers of mouse handler functions should remember that in the process world the mouse handler runs in its own process, and hence (a) you cannot depend on finding information on the stack (stash it in the window instead), and (b) while your function is running, the mouse is not available (if you have any non-trivial computation to do, spawn a process to do it, notify one of your existing processes to do it, or use PROCESS.EVAL to run it under some other process).

The following functions are meaningful even if the process world is not on: **BLOCK** (invokes the system background routine, which includes handling the mouse); TTY.PROCESS, THIS.PROCESS (both return NIL); and TTY.PROCESSP (returns T, i.e., anyone is allowed to take tty input). In addition, the following two functions exist in both worlds:

## (EVAL.AS.PROCESS FORM)

[Function]

Same as (ADD.PROCESS FORM 'RESTARTABLE 'NO), when processes are running, EVAL when not. This is highly

recommended for mouse functions that perform any non-trivial activity.

## (EVAL.IN.TTY.PROCESS FORM WAITFORRESULT)

[Function]

Same as (PROCESS.EVAL (TTY.PROCESS) FORM WAITFORRESULT), when processes are running, EVAL when not.

Most of the process functions that do not take a process argument can be called even if processes aren't running. ADD.PROCESS creates, but does not run, a new process (it runs when PROCESSWORLD is called).
